1. (10 points) Let $a$ be a real number. Consider the equation (where $x$ is the unknown)

$$4^{x^2-x} - a2^x - 4^x = 0.$$ 

Find the value(s) of $a$, for which this equation has exactly one real root.
2. (10 points) Let $a_1 = \frac{5}{20.17}\pi$ and define the sequence $(a_n)$ via $a_{n+1} = (\sin a_n)^2$ for $n \geq 1$. Show that this sequence $(a_n)_{n \geq 1}$ converges and find its limit.
3. (10 points) Let $a_1, \ldots, a_{2017}$ be real numbers, such that

$$a_1 + a_2 + \cdots + a_{2017} = 2017.$$ 

Find the maximal possible number of pairs $(i, j)$ ($1 \leq i < j \leq 2017$), such that $a_i + a_j < 2$. 
4. Let \( n \) be a positive integer less than 2014. Alice and Bob play the following game:

Alice chooses \( n \) distinct numbers among 2, 3, \ldots, 2017, and then Bob chooses another 2 distinct numbers from the remaining ones, and all \( n + 2 \) so chosen numbers are written down in increasing order:

\[
a_1 < a_2 < \cdots < a_{n+2}
\]

Bob wins if there are two consecutive numbers in this sequence, i.e. \( a_i \) and \( a_{i+1} \), for which \( a_i \) divides \( a_{i+1} \). Alice wins if there are no such two consecutive numbers.

Example: say \( n = 4 \), Alice choses 2, 3, 40, 70, Bob chooses 5, 90, then the numbers in increasing order are 2 < 3 < 5 < 40 < 70 < 90, and since 5|40 are consecutive we have that Bob wins this round. If Bob chose 90, 100 instead then the numbers are 2 < 3 < 40 < 70 < 90 < 100 and there no two consecutive numbers where the smaller divides the larger, so Alice wins.

(a) (5 points) Show that if \( n \geq 10 \), Alice has a winning strategy.

(b) (5 points) Show that if \( n \leq 9 \), Bob can always win the game.
5. (10 points) Let $M$ be a set of 2017 positive integers, and for each subset $A \subset M$ define a function $f(A)$ as the set of elements $m \in M$, for which the number of elements $a \in A$ dividing $m$, i.e. $\#\{a \in A : a|m\}$, is odd. For example, if $M = \{1, \ldots, 2017\}$ and $A = \{500, 1000, 2017\}$, then $f(A) = \{500, 1500, 2017\}$. Find the smallest number $k$ of colors, for which we can color each nonempty subset $A \subset M$ in one of these $k$ colors, such that whenever $A \neq f(A)$, then $A$ and $f(A)$ always have distinct colors.

(We are looking for the universal $k$, that works for any set $M$.)
