1 Introduction

The purpose of this paper is to begin an exploration of connections between
the Baum-Connes conjecture in operator K-theory and the geometric repre-
sentation theory of reductive Lie groups. Our initial goal is very modest, and
we shall not stray far from the realm of compact groups, where geometric
representation theory amounts to elaborations of the Weyl character formula
such as the Borel-Weil-Bott theorem. We shall recast the topological K-theory
approach to the Weyl character formula, due basically to Atiyah and Bott,
in the language of Kasparov’s KK-theory [Kas80]. Then we shall show how,
contingent on the Baum-Connes conjecture, our KK-theoretic Weyl character
formula can be carried over to noncompact groups.

The current form of the Baum-Connes conjecture is presented in [BCH94],
and the case of Lie groups is discussed there in some detail. On the face of
it, the conjecture is removed from traditional issues in representation theory,
since it concerns the K-theory of group $C^*$-algebras, and therefore projective
or quasi-projective modules over group $C^*$-algebras, rather than for example
irreducible $G$-modules. But an important connection with the representation
theory of reductive Lie groups was evident from the beginning. The conjec-
ture uses the reduced group $C^*$-algebra, generated by convolution operators
on $L^2(G)$, and as a result discrete series representations are projective in the
appropriate $C^*$-algebraic sense. In fact each discrete series contributes a dis-
tinct generator to $C^*$-algebra K-theory, and the Baum-Connes conjecture is
very closely related to the problem of realizing discrete series as spaces of
harmonic spinors on the symmetric space associated to $G$ (the quotient of
$G$ by a maximal compact subgroup $K$). Indeed this insight contributed in
an important way to the formulation of the conjecture in the first place. For
further discussion see [BCH94, Sec. 4] or [Laf02, Sec. 2].

We shall not be directly concerned here with either discrete series represen-
tations or the symmetric space. Instead the quotient space $G/K$ will appear
in connection with a comparison between $K$-equivariant and $G$-equivariant K-theory. We shall interpret the Baum-Connes conjecture as the assertion that a natural restriction map from $G$-equivariant KK-theory to $K$-equivariant KK-theory is an isomorphism. This will allow us to carry over calculations for the compact group $K$ to the noncompact group $G$.

We shall need to adopt definitions of KK-theory that are a bit different from those of Kasparov in [Kas80] and [Kas88]. We shall take as our starting point the concept, first used by Atiyah [Ati68], of a transformation from $K_G(X)$ to $K_G(Y)$ that is in a suitable sense continuous at the level of cycles, so that, for example, it extends to families of cycles and hence determines transformations

$$K_G(X \times Z) \longrightarrow K_G(Y \times Z).$$

The right sort of continuity can be captured fairly easily using the multiplicative structure of K-theory (there are other ways to do it as well). We define $KK_G(X,Y)$ to be the abelian group of all continuous transformations from $K_G(X)$ to $K_G(Y)$.

If $G$ is a compact group, then the equivariant $KK$-theory defined in this way has an extremely straightforward geometric character, sketched out in Section 2. It amounts to a framework in which to organize the basic constructions of Atiyah and Hirzebruch such as those in [AH59] that initiated K-theory. Moreover it happens that for reasonable spaces, such as the closed complex $G$-manifolds that we shall be considering, we recover Kasparov’s theory as a consequence of Poincaré duality. We hope that our discussion of these things in Section 2 will serve as a helpful introduction to KK-theory for some.

The utility of $KK$-theory is illustrated by the geometric approach to the Weyl character formula for a connected and compact Lie group. This is basically due to Atiyah and Bott in [AB68], but we shall give our own presentation of their ideas in Section 3. The main novelty is the interpretation of the numerator in the Weyl character formula in terms of intertwining operators. We shall also make additional remarks related to the Demazure character formula [Dem74] and the determination of the Kasparov ring $KK_G(B,B)$, where $B$ is the flag variety of $G$.

Here is a rapid summary of our Weyl character formula in equivariant $KK$-theory (or equivalently in Kasparov’s theory, since the groups involved are the same). There are intertwining operators

$$I_w : K_G(B) \longrightarrow K_G(B)$$

associated to each element of the Weyl group of $G$. There is a global sections operator

$$\Gamma : K_G(B) \longrightarrow K_G(pt).$$

given by the wrong-way map in K-theory determined by the collapse of $B$ to a point. According to the Atiyah-Singer index theorem, $\Gamma$ maps the K-theory class of a holomorphic $G$-vector bundle $E$ on $B$ to the alternating sum of the
Dolbeault cohomology groups on \( \mathcal{B} \) with coefficients in \( E \). Finally there is a localization operator

\[
\Lambda: K_G(\text{pt}) \longrightarrow K_G(\mathcal{B}).
\]

to each point of the flag variety \( \mathcal{B} \) there is associated a nilpotent subalgebra \( n \) of \( g \), and \( \Lambda \) takes a representation \( V \) to the alternating sum of the bundles on \( X \) with Lie algebra homology fibers \( H_*(n,V) \). We obtain elements

\[
\Lambda \in \mathbb{K}K_G(\text{pt}, \mathcal{B}), \quad \Gamma \in \mathbb{K}K_G(\mathcal{B}, \text{pt}), \quad \text{and} \quad I_{w} \in \mathbb{K}K_G(\mathcal{B}, \mathcal{B}),
\]

and we shall prove that

\[
\Gamma \otimes \Lambda = \sum_{w \in W} I_{w} \in \mathbb{K}K_G(\mathcal{B}, \mathcal{B}),
\]

while

\[
\Lambda \otimes \Gamma = |W| \cdot \text{Id} \in \mathbb{K}K_G(\text{pt}, \text{pt}).
\]

Here \( \otimes \) is the Kasparov product—composition of transformations, but written in the reverse order. The connection to Weyl’s formula will be clear to experts, but is in any case explained in Section 3.4.

Now let \( G \) be a connected linear reductive Lie group, let \( \mathcal{B} \) be the complex flag variety associated to \( G \), and let \( K \) be a maximal compact subgroup of \( G \). There is a restriction functor

\[
\mathbb{K}K_G(X,Y) \longrightarrow \mathbb{K}K_K(X,Y)
\]

in (our version of) equivariant KK-theory, and, as we noted above, the Baum-Connes conjecture is equivalent to the assertion that the restriction functor is an isomorphism. So if we assume the Baum-Connes conjecture, then we can argue, by passing from a compact form \( G_{\text{comp}} \) of \( G \) to the subgroup \( K \subseteq G_{\text{comp}} \), and then to \( G \) itself by means of the restriction isomorphism (1), that the Weyl character formulas given above carry over to \( G \)-equivariant KK-theory. In doing so, we shall use the full strength of the KK-theoretic Weyl character formula. The resulting formulas could be thought of as a K-theoretic version of the character formula of Osborne [Osb74, Cas77, HS83], although we shall not explore that here. They also call to mind the mechanisms of geometric representation theory [BB81, Be˘ ı84], involving as they do a “localization functor” \( \Lambda \) and a “global sections functor” \( \Gamma \) that are essentially inverse to one another (at the level of \( W \)-invariants).

Among our longer term goals are refinements of the Weyl character formulas presented here, perhaps using concepts from [Blo10], that seek to bridge between analytic tools familiar in the Baum-Connes theory and tools familiar in geometric representation theory. This larger project we are pursuing in collaboration with David Ben-Zvi and David Nadler.

**Acknowledgements**

We would like to thank David Ben-Zvi, Dragan Milicic, David Nadler and David Vogan for stimulating and helpful conversations on aspects of this paper.
2 Basic KK-Theory

In this section we shall review some basic constructions in topological K-theory, and then recast them within KK-theory. We shall do so partly to introduce KK-theory from a geometric point of view that might appeal to some, and partly to set the stage for a discussion of the Baum-Connes conjecture in the last section of the paper.

2.1 Very Basic K-Theory

If $X$ is a compact Hausdorff space, then the Atiyah-Hirzebruch topological K-theory group $K(X)$ is the Grothendieck group of complex vector bundles on $X$. The pullback operation on vector bundles makes $K(X)$ into a contravariant functor, and indeed a contravariant homotopy functor. See for example [Ati67].

The K-theory functor extends to the category of locally compact Hausdorff spaces. In this category the morphisms from $W$ to $Z$ are the continuous maps from the one-point compactification of $W$ to the one-point compactification of $Z$. For example if $U$ is an open subset of a locally compact space $X$, then the map that collapses the complement of $U$ in $X$ to the point at infinity gives a map

$$K(U) \longrightarrow K(X). \quad (2)$$

We'll call this the pushforward from $K(U)$ to $K(X)$.

A compactly supported and bounded complex of vector bundles

$$E_0 \leftarrow E_1 \leftarrow \cdots \leftarrow E_k \quad (3)$$

over a locally compact space $W$ determines an element of $K(W)$. Here the support of a complex is the complement of the largest open set in the base over which each complex of fibers is exact. In fact $K(W)$ may be completely described in terms of such complexes; see [Seg68] or [AS68].

**Example 2.1.** Let $V$ be a vector bundle over a locally compact base space. Consider the following complex over the total space of $V$, in which the indicated bundles have been pulled back from the base to the total space:

$$\wedge^0 V^* \xleftarrow{\iota_v} \wedge^1 V^* \xleftarrow{\iota_v} \cdots \xleftarrow{\iota_v} \wedge^\text{top} V^*. \quad (4)$$

The differentials at $v \in V$ are given by contraction with the radial field on $V$. This is the section of the pullback of $V$ whose value at the point $v$ is the vector $v$. The complex (4) is exact except at the set of zero vectors. So if the base is compact, then the complex is compactly supported and hence determines an element of $K(V)$, called the *Thom element*. As a special case, if the original base space is a point, then we obtain the *Bott element* in $K(V)$.

Returning to the case of a general complex (3), we obtain a class in $K(U)$ for any open subset $U$ of the base that contains the support of the complex. These $K(U)$-class are related on one another (as the open set $U$ varies) by pushforward maps.
2.2 Products and KK-Groups

Continuing our review, the tensor product operation on vector bundles over compact spaces determines a functorial and associative product operation

\[ K(X) \otimes K(Y) \rightarrow K(X \times Y). \]  

(5)  

\[ \text{eq-k-theory-prod} \]

We'll denote the product by \( E \boxtimes F \). The product of two K-theory classes given by compactly supported complexes is given by the tensor product of complexes.

Combining (5) with restriction to the diagonal in \( X \times X \), we find that \( K(X) \) carries the structure of a commutative ring. More generally, associated to a map \( Y \rightarrow X \) there is a \( K(X) \)-module structure on \( K(Y) \). We'll write this product as \( E \cdot F \). If \( X \) is compact then the class \( 1_X \in K(X) \) of the trivial rank-one bundle is a multiplicative identity in \( K(X) \).

For the purposes of the following definition fix the locally compact spaces \( X \) and \( Y \) and consider the groups

\[ K(X \times Z) \quad \text{and} \quad K(Y \times Z) \]

as contravariant functors in the \( Z \)-variable.

**Definition 2.2.** A natural transformation

\[ T_Z : K(X \times Z) \rightarrow K(Y \times Z) \]  

is continuous if each \( T_Z \) is a \( K(Z) \)-module homomorphism.

(6)  

\[ \text{eqn-cont-tr1} \]

The term “continuous” has been chosen to suggest that \( T \) is a means to construct (virtual) vector bundles on \( Y \) from vector bundles on \( X \) that is continuous in the sense that it extends to families (think of a vector bundle on \( X \times Z \) as a family of vector bundles on \( X \) parametrized by \( Z \)).

**Remark 2.3.** Equivalently, \( T \) is continuous if all diagrams of the form

\[ \begin{array}{ccc} K(X \times Z) \otimes K(W) & \xrightarrow{T_Z \otimes \text{Id}} & K(Y \times Z) \otimes K(W) \\ \downarrow & & \downarrow \\ K(X \times Z \times W) & \xrightarrow{T_{Z \times W}} & K(Y \times Z \times W) \end{array} \]  

(7)  

\[ \text{eqn-cont-tr2} \]

are commutative.

**Definition 2.4.** Denote by \( KK(X, Y) \) the abelian group of continuous transformations from \( K(X) \) to \( K(Y) \).

**Remark 2.5.** This is not Kasparov’s definition of KK-theory \([\text{Kas80}]\). However Kasparov’s KK-groups are closely related to our \( KK \)-groups, and indeed they are the same in many cases; see Section 2.7.
It is evident that there is an associative “product” operation

\[ \mathbb{K}K(X, Y) \otimes \mathbb{K}K(Y, Z) \to \mathbb{K}K(X, Z) \]  

(8)  

\[ \text{eq-kasp-prod} \]

given by composition of transformations. This is the Kasparov product, and using it we obtain an additive category whose objects are locally compact spaces and whose morphisms are continuous transformations. However the Kasparov product of elements

\[ S \in \mathbb{K}K(X, Y) \quad \text{and} \quad T \in \mathbb{K}K(Y, Z) \]

is conventionally denoted

\[ S \otimes T \in \mathbb{K}K(X, Z), \] 

(9)  

\[ \text{eq-kasp-prod2} \]

which is opposite to the notation \( T \circ S \) for composition of morphisms in a category.

In addition to the Kasparov product (8), there is by definition a pairing

\[ \mathbb{K}K(X) \otimes \mathbb{K}K(X, Y) \to \mathbb{K}K(Y) \] 

(10)  

\[ \text{eq-kasp-prod-k-thy} \]

given by the action of continuous transformations on K-theory. We’ll use the same symbol \( \otimes \) for it, and indeed it can be viewed as a special case of the Kasparov product since the evaluation of the pairing

\[ \mathbb{K}K(pt) \otimes \mathbb{K}K(pt, Y) \to \mathbb{K}(Y) \]

on the unit element \( 1_{pt} \in \mathbb{K}(pt) \) gives an isomorphism of abelian groups

\[ \mathbb{K}K(pt, Y) \cong \mathbb{K}(Y). \]

Some examples of continuous transformations, and hence \( \mathbb{K}K \)-classes, immediately suggest themselves.

\textit{Example 2.6.} If \( f: Y \to X \) is a continuous and proper map, then the pullback construction for vector bundle determines a class

\[ [X \xleftarrow{f} Y] \in \mathbb{K}K(X, Y). \] 

(11)  

\[ \text{eq-pullback-class} \]

If \( g: Z \to Y \) is another continuous and proper map, then

\[ [X \xleftarrow{f} Y] \otimes [Y \xrightarrow{g} Z] = [X \xleftarrow{fg} Z]. \]

\textit{Example 2.7.} A complex vector bundle \( E \) on a compact space \( X \), or more generally a class in \( \mathbb{K}(X) \), where \( X \) is any locally compact space, determines a continuous transformation

\[ [E] \in \mathbb{K}K(X, X) \] 

(12)  

\[ \text{eq-vb-class} \]
by multiplication using the product \( \cdot \) in K-theory.\(^3\) We obtain in this way an injective ring homomorphism
\[
K(X) \rightarrow KK(X, X),
\] (13)
where the multiplication in the ring \( KK(X, X) \) is of course the Kasparov product.

**Example 2.8.** If \( V \) is a complex vector bundle over a locally compact space \( W \), then the *Thom homomorphism*

\[
Th: K(W) \rightarrow K(V)
\]
is given by pullback to \( V \) (of vector bundles or complexes of vector bundles initially defined on \( W \)) followed by product with the Thom complex (4). Note that even when \( W \) is merely locally compact, the result is a compactly supported complex, because the support of a tensor product of complexes is the intersection of the supports of the factors. If \( Z \) is an auxiliary space, then by pulling back \( V \) to \( W \times Z \) we obtain in addition a Thom homomorphism
\[
Th_Z: K(W \times Z) \rightarrow K(V \times Z).
\] (14)
Collectively these define a continuous transformation \( Th \in KK(W, V) \).

**Remark 2.9.** The concept of continuous transformation (although not the name) has its origins in Atiyah’s elliptic operator proof of Bott periodicity [Ati68]. Let \( V \) be a finite-dimensional complex vector space. According to Atiyah’s famous rotation trick, if two continuous transformations
\[
K(pt) \rightarrow K(V) \quad \text{and} \quad K(V) \rightarrow K(pt)
\]
compose to give the identity on \( K(pt) \), then they compose the other way to give the identity on \( K(V) \) (and thereby implement Bott periodicity).

For later purposes we note the following fact:

**Lemma 2.10.** Every continuous transformation is functorial with respect to Thom homomorphisms.

**Proof.** We mean that if \( V \) is a complex vector bundle over a locally compact space \( W \), and if \( T \in KK(X, Y) \), then the diagram
\[
\begin{array}{ccc}
K(X \times W) & \xrightarrow{T_W} & K(Y \times W) \\
\downarrow{Th_X} & & \downarrow{Th_Y} \\
K(X \times V) & \xrightarrow{T_V} & K(Y \times V)
\end{array}
\]

\(^3\) We shall reserve the square bracket notation \([ \ ]\) for \( KK \)-classes, and avoid it for K-theory classes.
is commutative. If \( W \) is compact, so that the Thom class is defined in \( K(V) \), then this is a consequence of the definition of continuous transformation (in the form given in Remark 2.3). The noncompact case can be reduced to the compact case. \( \square \)

2.3 Wrong-Way Maps

Let \( X \) and \( Y \) be complex or almost-complex manifolds (without boundary) and let \( f : X \to Y \) be any continuous map. There is an associated wrong-way class

\[
[X \xrightarrow{f} Y] \in KK(X, Y), \tag{15}
\]

which determines a wrong-way map from \( K(X) \) to \( K(Y) \). The construction, which is due to Atiyah and Hirzebruch, is based on the Thom homomorphism and Bott periodicity.

Recall that the normal bundle of an embedding of manifolds \( h : X \to Z \) is the quotient real vector bundle

\[
N_Z X = h^*TZ / TX, \tag{16}
\]

where the derivative of \( h \) is used to embed \( TX \) into \( h^*TZ \). If \( X \) is almost-complex, then way embed \( X \) equivariantly into a finite-dimensional complex \( G \)-vector space \( V \) in such a way that the normal bundle \( N_V X \) admits a complex vector bundle structure for which there is an isomorphism

\[
N_V X \oplus TX \cong V \times X \tag{17}
\]

of complex vector bundles. The normal bundle for the diagonal map of \( X \) into \( Y \times V \) is as follows:

\[
N_{Y \times V} X \cong f^*TY \oplus N_V X \tag{18}
\]

(from the definition (16) there is a natural projection map from the left-hand side onto \( N_V X \), and a natural isomorphism from \( f^*TY \) onto the kernel of this projection). In particular it too is endowed with a complex structure. The wrong way map from \( K(X) \) to \( K(Y) \) is by definition the composition

\[
K(X) \to K(N_{Y \times V} X) \to K(Y \times V) \to K(Y), \tag{19}
\]

in which the first map is the Thom homomorphism, the second is induced from an embedding of the normal bundle as a tubular neighborhood, and the last is the Bott periodicity isomorphism. Each map in (19) is given by some \( KK \)-class, and the Kasparov product of these is the wrong-way class (15).

The wrong-way class depends only on the homotopy class of \( f \) and is functorial with respect to ordinary composition of smooth maps:

\[
[X \xrightarrow{f} Y] \otimes [Y \xrightarrow{g} Z] = [X \xrightarrow{g \circ f} Z] \in KK(X, Z).
\]
Example 2.11. Wrong-way maps in K-theory (and for that matter K-theory itself) were introduced by Atiyah and Hirzebruch in [AH59] to prove integrality theorems for characteristic numbers.\textsuperscript{4} It may be calculated that if $X$ is a closed almost-complex manifold, and if $E$ is a complex vector bundle on $X$, then the wrong-way map associated to $X \to \text{pt}$ sends the K-theory class of $E$ to

$$\pi_*(E) = \int_X \text{Todd}(TM) \text{ch}(E) \cdot 1_{\text{pt}} \in K(\text{pt}).$$

(20) \textit{eqn-rr}

As a result the integral is always an integer.

Example 2.12. If $U \to X$ is the embedding of an open subset into $Y$, then the wrong-way class $[U \to X]$ is the same as the class $[U \leftarrow X]$ associated to the pushforward construction of Example 2.

Example 2.13. The wrong-way map for the inclusion of the zero section in a complex vector bundle is the Thom homomorphism. The fact that it is an isomorphism reflects the fact that the section map is a homotopy equivalence.

The wrong-way classes are related to the pullback classes of (11) in a number of ways, of which the most important is this:

\textbf{Lemma 2.14.} If in the diagram

$$\begin{array}{ccc}
Z \times_Y W & \to & W \\
\downarrow & & \downarrow \\
Z & \to & Y
\end{array}$$

of almost-complex manifolds the map from $Z$ to $Y$ is a submersion, then

$$[Z \to Y] \otimes [Y \leftarrow W] = [Z \leftarrow Z \times_Y W] \otimes [Z \times_Y W \to W]$$

(21) \textit{eq-base-change}

in $\mathbb{K}K(Z,W)$. \hfill \qed

2.4 Poincaré Duality

We shall calculate $\mathbb{K}K(X,Y)$ when $X$ and $Y$ are closed (almost) complex manifolds.

\textbf{Lemma 2.15.} Continuous transformations are functorial for wrong-way maps in K-theory.

\textit{Proof.} The assertion in the lemma is that if $T \in \mathbb{K}K(X,Y)$, and if $f: W \to Z$ is a continuous map between almost-complex manifolds, then the diagram

\textsuperscript{4} Actually the construction of wrong-way maps was only conjectural at the time that [AH59] was written, but see Karoubi’s book [Kar78] for a full exposition.
\[
\begin{array}{ccc}
K(X \times W) & \xrightarrow{T_W} & K(Y \times W) \\
\downarrow f_* & & \downarrow f_* \\
K(X \times Z) & \xrightarrow{T_Z} & K(Y \times Z)
\end{array}
\]

in which the vertical arrows are wrong-way maps, is commutative. This follows from functoriality with respect to the Thom homomorphism, as described in Lemma 2.10. □

Denote by \( \Delta_X \in K(X \times X) \) the image of the unit class \( 1_X \in K(X) \) under the wrong-way map induced from the diagonal map \( \delta: X \to X \times X \):

\[
\Delta_X := 1_X \otimes [X \xrightarrow{\delta} X \times X] \in K(X \times X).
\] (22)

**Definition 2.16.** Let \( Y \) be any locally compact space. The Poincaré duality homomorphism

\[
\hat{T}: \mathbb{K}\mathbb{K}(X,Y) \longrightarrow K(Y \times X)
\] (23)

is defined by means of the formula

\[
\hat{T} = T_X(\Delta_X) \in K(Y \times X),
\]

where \( T \in \mathbb{K}\mathbb{K}(X,Y) \).

**Example 2.17.** The Poincaré dual of a wrong-way class \( [X \xrightarrow{f} Y] \in K\mathbb{K}(X,Y) \) is the class

\[
1_X \otimes [X \to Y \times X] \in K(Y \times X)
\]

obtained from the embedding of \( X \) into \( Y \times X \) as the graph of \( f \).

**Proposition 2.18.** The Poincaré duality homomorphism (23) is an isomorphism of abelian groups.

**Proof.** A duality map in the reverse direction,

\[
K(Y \times X) \longrightarrow \mathbb{K}\mathbb{K}(X,Y),
\] (24)

may be defined by sending a vector bundle (or K-theory class) \( E \) on \( Y \times X \) to the Kasparov product

\[
[X \leftarrow Y \times X] \otimes [E] \otimes [X \times Y \to Y] \in \mathbb{K}\mathbb{K}(X,Y).
\]

Applying first (23) and then (24) we obtain from a continuous transformation \( T \in \mathbb{K}\mathbb{K}(X,Y) \) the continuous transformation

\[
K(X) \ni a \mapsto p_*(\langle 1_Y \boxtimes a \rangle \cdot T_X(\Delta_X)) \in K(Y),
\] (25)

where \( p_*: K(Y \times X) \to K(Y) \) is the wrong way map associated to the projection
\( \pi: Y \times X \to Y \)

onto the first factor (to keep the notation simple we are suppressing the auxiliary space \( Z \)). By definition of continuous transformation, the right-hand side of (25) is equal to

\[ p_\ast(T_X((1_X \boxtimes a) \cdot \Delta_X)). \]  

(26)

Now

\[ (a \boxtimes 1_X) \cdot \Delta_X = (1_X \boxtimes a) \cdot \Delta_X \]  

(27)

because the class \( \Delta_X \in K(X \times X) \) is supported on the diagonal, and because the two coordinate projections from \( X \times X \) to \( X \) are homotopic in a neighborhood of the diagonal. Using (27) together with Lemma 2.15, we find that (26) is equal to \( T(q_\ast(\Delta_X) \cdot a) \), where \( q_\ast \) is the wrong-way map associated to the projection

\[ q: X \times X \to X \]

onto the first factor. Since \( q_\ast(\Delta_X) = 1_X \), we recover from (25) the continuous transformation \( T \) with which we began, as required.

The calculation of the composition of the two duality maps in the other order is similar. \( \square \)

Remark 2.19. A similar discussion is possible for manifolds with boundary. Suppose that \( X \) is a compact almost-complex manifold with boundary, and denote by \( X \) its interior. Define a modified diagonal map

\[ \overline{X} \to X \times X \]

\[ x \mapsto (x, f(x)) \]

using any \( f: \overline{X} \to X \) for which the compositions

\[ \overline{X} \to X \to \overline{X} \quad \text{and} \quad X \to \overline{X} \to X \]

with the inclusion of \( X \) into \( \overline{X} \) are homotopic to the identity (for example, define \( f \) by deforming a closed collar of the boundary into its interior). Define \( \Delta_X \in K(\overline{X} \times X) \) to the image of the class \( 1_{\overline{X}} \in K(\overline{X}) \) under the associated wrong way map, and then define the \textit{Poincaré-Lefschetz duality map}

\[ \hat{\cdot}: \text{KK}(\overline{X}, Y) \to K(Y \times X) \]  

(28)

by the same formula as before. It too is an isomorphism, by the same argument as before.

2.5 Equivariance with Respect to a Compact Group

If \( G \) is a compact Hausdorff group, and if \( X \) is a compact or locally compact Hausdorff \( G \)-space, then we can form the equivariant topological \( K \)-theory group \( \text{K}_G(X) \); see [Seg68]. We can repeat our discussion up to now using
$K_G(X)$ in place of $K(X)$ (and, for example, equivariant continuous maps between complex $G$-manifolds, and so on), including the definition of equivariant groups $\mathbb{K}K_G(X,Y)$ comprised of continuous transformations from the equivariant K-theory of $X$ to the equivariant K-theory of $Y$. Our discussion carries through without change.

New issues arise related to restriction and induction. If $H$ is a closed subgroup of $G$, then there is a restriction map

$$K_G(X) \rightarrow K_H(X)$$

that forgets $G$-equivariance and retains only $H$-equivariance. In the other direction there is an induction map

$$K_H(X) \rightarrow K_G(\text{Ind}_H^G X).$$

Here $\text{Ind}_H^G X$ is the quotient of $G \times X$ by the $H$-action $h \cdot (g,x) \mapsto (gh^{-1},hx)$, and the induction map is obtained by associating to an $H$-equivariant bundle $E$ over $X$ the $G$-equivariant bundle $\text{Ind}_H^G E$ over $\text{Ind}_H^G X$. The induction map (30) is an isomorphism: its inverse is given by restriction, followed by pulling back along the $H$-equivariant map from $X$ into $\text{Ind}_H^G X$ that sends $x \in X$ to $(e,x) \in \text{Ind}_H^G X$.

Using the induction isomorphism (30) we define a restriction homomorphism

$$\text{Res}^G_H : \mathbb{K}K_G(X,Y) \rightarrow \mathbb{K}K_H(X,Y)$$

as follows. If $X$ is a $G$-space and $Z$ is an $H$-space, then there is a $G$-equivariant homeomorphism

$$\text{Ind}^G_H(X \times Z) \xrightarrow{\cong} X \times \text{Ind}^G_H Z$$

induced from $(g,x,z) \mapsto (gx,g,z)$. If $T \in \mathbb{K}K_G(X,Y)$, then define a continuous transformation in $H$-equivariant K-theory by means of the diagram

$$
\begin{array}{ccc}
K_H(X \times Z) & \xrightarrow{(\text{Res}^G_H T)_z} & K_H(Y \times Z) \\
\cong & & \cong \\
K_G(\text{Ind}^G_H(X \times Z)) & \xrightarrow{=} & K_G(\text{Ind}^G_H(Y \times Z)) \\
\cong & & \cong \\
K_G(X \times \text{Ind}^G_H Z) & \xrightarrow{T_{\text{Ind}^G_H z}} & K_G(Y \times \text{Ind}^G_H Z).
\end{array}
$$

The pullback, vector bundle and wrong-way $\mathbb{K}K_G$-classes defined in (11), (12) and (15) are mapped to like $\mathbb{K}K_H$-classes obtained by forgetting $G$-equivariant structure and retaining only $H$-equivariant structure. Moreover restriction from $\mathbb{K}K_G$ to $\mathbb{K}K_H$ is compatible with Kasparov product.
Remark 2.20. Note for later use that the definition of the restriction homomorphism in KK does not involve the restriction homomorphism in K-theory.

There is also an induction homomorphism

$$\text{Ind}_G^H : \mathbb{K}K_H(X, Y) \longrightarrow \mathbb{K}K_G(\text{Ind}_H^G X, \text{Ind}_H^G Y)$$  \hspace{1cm} (34)  

that is defined in a very similar way, by means of the commuting diagram

\[
\begin{array}{ccc}
K_H(X \times Z) & \xrightarrow{T_Z} & K_H(Y \times Z) \\
\cong & & \cong \\
K_G(\text{Ind}_H^G(X \times Z)) & \cong & K_G(\text{Ind}_H^G(Y \times Z)) \\
\cong & & \cong \\
K_G(\text{Ind}_H^G X \times Z) & \xrightarrow{(\text{Ind}_H^G T_Z)} & K_G(\text{Ind}_H^G Y \times Z).
\end{array}
\]

Here $Z$ is a $G$-space, viewed in the top row as an $H$-space by restriction. The top vertical maps are the induction isomorphisms (30) and the bottom result from the identifications

$$\text{Ind}_H^G(X \times Z) \cong \text{Ind}_H^G X \times Z$$

given by $(g, x, z) \mapsto (g, x, gz)$. The induction map is compatible with the construction of pullback and vector bundle classes in (11) and (12). If $G/H$ is given a $G$-invariant almost-complex structure (should one exist), then $\text{Ind}_H^G X$ will acquire a $G$-invariant almost-complex structure from an $H$-invariant almost-complex structure on $X$, and the induction map becomes compatible with the wrong-way classes (15) too.

Neither (31) nor (34) is an isomorphism. But if $X$ is a $G$-space and $Y$ is an $H$-space, then the hybrid map

$$\text{IndRes} : \mathbb{K}\mathbb{K}_G(X, \text{Ind}_H^G Y) \longrightarrow \mathbb{K}\mathbb{K}_H(X, Y)$$  \hspace{1cm} (35)  

that is obtained by first restricting from $G$ to $H$, as in (31), and then restricting to the subspace $Y \subseteq \text{Ind}_H^G Y$, is an isomorphism. Its inverse is defined by means of the diagram

\[
\begin{array}{ccc}
K_G(X \times Z) & \xrightarrow{\text{IndRes}^{-1} T_Z} & K_G(\text{Ind}_H^G Y \times Z) \\
\cong & & \cong \\
K_G(\text{Ind}_H^G(Y \times Z)) & \cong & \text{induction} \\
\text{restriction} & & \\
K_H(X \times Z) & \xrightarrow{T_Z} & K_H(Y \times Z).
\end{array}
\]
In particular, we find that if the action of $H$ on $Y$ extends to $G$, then restriction to $H$ followed by restriction to $eH \subseteq G/H$ gives an isomorphism

$$\mathbb{K}K_G(X, G/H \times Y) \cong \mathbb{K}K_H(X, Y).$$  \hfill (36)  

### 2.6 The Index Theorem

Let $X$ be a complex (or almost-complex) $G$-manifold. The index map for the Dolbeault operator on $X$ is a homomorphism from $K^G(X)$ to $K^G(pt)$, and it extends by a families index construction to a continuous transformation

$$\text{Index}_Z : K^G(X \times Z) \to K^G(Z).$$

The Atiyah-Singer index theorem asserts that

$$\text{Index} = [X \to pt] \in \mathbb{K}K^G(X, pt).$$

For example, the characteristic class formula of Example 2.11 describes the index of the Dolbeault operator on a closed complex manifold $X$ (without group action) with coefficients in a smooth complex vector bundle $E$.

More generally the Atiyah-Singer index theorem for families asserts that if $p : Z \to Y$ is a submersion of closed, complex manifolds, then the class

$$[Z \xleftarrow{p} Y] \in \mathbb{K}K^G(Z, Y)$$

is equal to the index class associated to the family of Dolbeault operators on the fibers of $p$.

### 2.7 Kasparov's Analytic KK-Theory

Kasparov’s KK-groups [Kas80] have their origins in the Atiyah-Janich theorem describing $K$-theory in terms of families of Fredholm operators [Ati69, Jän65], and in Atiyah’s attempt to define $K$-homology in terms of “abstract elliptic operators” [Ati70]; see [Hig90] for an introduction. By design, there is a natural transformation

$$\mathbb{K}K^G(X, Y) \to \mathbb{K}K^G(X, Y)$$  \hfill (37)  

that is compatible with Kasparov products. The classes in (11), (12) and (15) all have counterparts in Kasparov theory, from which it follows that KK-theory satisfies Poincaré duality in the way that we described in Section 2.4 (in fact see [Kas88, Sec. 4] for much more general formulations of Poincaré duality). As a result, the map (37) is an isomorphism whenever $X$ is a compact almost-complex $G$-manifold (possibly with boundary). A bit more generally, if $X$ is a $G$-ENR (see for example [Die79]) then $X$ is a $G$-retract of a compact almost-complex $G$-manifold with boundary, namely a suitable compact neighborhood in Euclidean space, and we see again that (37) is an isomorphism.
Kasparov’s KK-theory gives a means to conveniently formulate and prove the Atiyah-Singer index theorems reviewed in the previous section. But the real strength of KK-theory only becomes apparent when dealing with equivariant K-theory for noncompact groups $G$ [Kas88], where it provides a set of tools that operate beyond the reach of the rather simple ideas we have been developing up to now. We shall take up this point (in a somewhat idiosyncratic way) in the last section of this paper.

3 Weyl Character Formula

Let $G$ be a compact connected Lie group. Our aim is to present a K-theoretic account of the Weyl character formula for $G$, more or less along the lines of [AB68], but in a slightly more general context.

3.1 A First Look at KK-Theory for the Flag Variety

The Weyl character formula calculates the restrictions to a maximal torus $T \subseteq G$ of the characters of irreducible representations of $G$. So in K-theory terms it concerns the map

$$K_G(pt) \rightarrow K_G(G/T)$$

(38)

given by pulling back vector bundles over a point (that is, representations) to vector bundles over the homogeneous space $G/T$.

One reason for recasting the character formula in these terms is that the manifold $G/T$ carries a $G$-invariant complex structure, using which the machinery of the previous sections can be applied. For the time being let us frame this as follows: there is a complex $G$-manifold $B$ and a $G$-equivariant diffeomorphism between $B$ and $G/T$. We shall recall the construction of $B$ (the flag variety) in the next section.

Consider then the K-theory classes

$$[pt \leftarrow B] \in \mathbb{K}K_G(pt, B)$$

and

$$[B \rightarrow pt] \in \mathbb{K}K_G(B, pt).$$

Kasparov product with the first gives the restriction map (38). It turns out that Kasparov product with the second gives a one sided inverse, and indeed

$$[pt \leftarrow B] \otimes [B \rightarrow pt] = \text{Id} \in \mathbb{K}K_G(pt, pt).$$

(39)

This was first observed by Atiyah [Ati68, Prop. 4.9] and we shall check it later (see Remark 3.5). So (38) embeds $K_G(pt)$ as a summand of $K_G(B)$. Equivalently, if $T$ is a maximal torus in $G$, then the restriction map
between representation rings is an embedding onto a direct summand.

Define
\[ \Pi = [\mathcal{B} \to \text{pt}] \otimes [\text{pt} \to \mathcal{B}] \in \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}). \tag{40} \]

It follows from (39) that \( \Pi \) is an idempotent in the Kasparov ring \( \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}) \), and the problem of determining the representation ring \( K_G(\text{pt}) \) becomes (to a certain extent, at least) the problem of usefully describing the idempotent \( \Pi \in \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}) \). We shall give one solution in the next section.

### 3.2 Intertwining Operators

Because it is a homogeneous space, every \( G \)-equivariant map from \( \mathcal{B} \) to itself is a diffeomorphism. The \( G \)-equivariant self-maps of \( \mathcal{B} \) therefore assemble into a group \( W \), but we’ll do so using the opposite of the usual composition law for maps, so as to obtain a right-action of \( W \) on \( \mathcal{B} \):

\[ F \times W \ni (b, w) \mapsto b \cdot w \in \mathcal{B}. \tag{41} \]

This is the Weyl group of \( G \). In other words, the Weyl group is the opposite of the usual group of \( G \)-equivariant self-maps. It is a finite group.

If a base-point \( \text{pt} \in \mathcal{B} \) is chosen, and if \( T \) is the maximal torus that fixes the base-point, then under the resulting identification \( \mathcal{B} \cong G/T \), the action (41) takes the form

\[ G/T \times N(T)/T \ni (gT, wT) \mapsto gwT \in G/T, \]

where \( N(T) \) is the normalizer of \( T \) in \( G \). This explains our preference for right actions in the definition of the Weyl group. Right actions also match nicely with the Kasparov product: each Weyl group element determines a wrong-way class

\[ I_w = [\mathcal{B} \xrightarrow{w} \mathcal{B}] \in \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}), \tag{42} \]

and we obtain a homomorphism from \( W \) into the group of invertible elements in the ring \( \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}) \). We’ll call the elements \( I_w \in \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}) \) intertwining operators and we shall analyze them further in Section 3.5.

### 3.3 Weyl Character Formula in KK-Theory

The ring \( \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}) \) contains the intertwiners \( I_w \) from (42) as well as the classes (12) associated to \( G \)-equivariant vector bundles on \( \mathcal{B} \). Our aim is to calculate the element \( \Pi \) from (40) in terms of these ingredients.

We shall use the vector bundle class

\[ [\wedge^* T^* \mathcal{B}] \in \mathbb{K}\mathbb{K}_G(\mathcal{B}, \mathcal{B}). \]
Here $T^*B$ is the complex dual of the tangent bundle $TB$, and we take degree into account, so that

$$\langle \wedge^p T^* B \rangle := \sum (-1)^p [\wedge^p T^* B] \in KK_G(B, B).$$

The representation-theoretic significance of this class will be reviewed in the next section. Its geometric significance is as follows. Let $X$ be any closed complex or almost-complex manifold equipped with a smooth action of a compact torus $T$. The $T$-fixed point set $F \subseteq X$ is a submanifold and it inherits an almost-complex structure from $X$.

**Lemma 3.1.** If $F \to X$ is the inclusion of the fixed-point manifold, then

$$\wedge^p T^* X = \wedge^p T^* F \otimes [F \to X] \in K_T(X),$$

and

$$\langle \wedge^* T^* X \rangle = [X \leftarrow F] \otimes [\wedge^* T^* F] \otimes [F \to X] \in KK_T(X, X).$$

**Proof.** Fix a $T$-invariant Hermitian metric on $X$. Pick a vector $v$ in the Lie algebra of $T$ such that $\exp(v)$ topologically generates the torus $T$, and denote by $v^X$ the associated Killing vector field on $X$. Its zero set is precisely $F$. Let $N$ be the normal bundle of $F$. The torus $T$ also acts on $N$, and the element $v \in \text{Lie}(T)$ determines a vertical vector field $v^N$ on $N$. The zero set of $v^N$ is precisely the set $F \subseteq N$ of zero vectors in $N$.

The element $\wedge^* T^* X \in K_T(X)$ is the class of the complex of vector bundles

$$\wedge^0 T^* X \leftarrow v^X \wedge^1 T^* X \leftarrow v^X \ldots$$

on $X$ (since $X$ is compact the differentials are actually irrelevant to the K-theory class). The support of the complex is $F$, and we find that $\wedge^* T^* X$ is equal to the pushforward (via a tubular neighborhood embedding) of the class in $K_T(N)$ associated to the complex

$$\wedge^0 T^* X \leftarrow_{v^N} \wedge^1 T^* X \leftarrow_{v^N} \ldots$$

Here the bundles $\wedge^p T^* X$, originally defined on $X$, are restricted to $F$ then pulled back to $N$. On the other hand, the class $\wedge^* T^* F \otimes [F \to X]$ is the pushforward from $N$ to $X$ of the class associated to the complex

$$\wedge^0 T^* X \leftarrow r \wedge^1 T^* X \leftarrow r \ldots$$

where $r$ is the radial vector field from Example 2.1 and (4). But the vertical tangent vector fields $v^N$ and $r$ are pointwise linearly independent, in fact orthogonal in the underlying euclidean metric, everywhere away from the zero vectors in $N$. So the complexes (46) and (47) are homotopic through complexes with support $F \subseteq N$ and therefore determine the same K-theory class. Equation (44) is a consequence of (43). □
In the case of the flag variety, where \( F \) is zero-dimensional, Lemma 3.1 implies that
\[
\left[ \wedge^* T^* B \right] = \left[ B \leftarrow F \right] \otimes \left[ F \rightarrow B \right] \in \KK_T(B, B). \tag{48} \]
This leads to the following formulas:

**Theorem 3.2 (Weyl Character Formula in KK-Theory).**

\[
\left[ pt \leftarrow B \right] \otimes \left[ \wedge^* T^* B \right] \otimes \left[ B \rightarrow pt \right] = |W| \cdot \left[ pt \rightarrow pt \right] \in \KK_T(pt, pt) \tag{49} \]
and
\[
\left[ B \rightarrow pt \right] \otimes \left[ pt \leftarrow B \right] \otimes \left[ \wedge^* T^* B \right] = \sum_{w \in W} \left[ B \xrightarrow{w} B \right] \in \KK_G(B, B). \tag{50} \]

**Proof.** The restriction map
\[
\KK_G(pt, pt) \rightarrow \KK_T(pt, pt)
\]
is injective, and so we can prove (49) by calculating in \( T \)-equivariant KK-theory. Inserting (44) into the left hand side of (49) gives
\[
\left[ pt \leftarrow F \right] \otimes \left[ F \rightarrow pt \right] \in \KK_T(pt, pt),
\]
which is equal to \( |W| \cdot \left[ pt \rightarrow pt \right] \), as required.

To prove (50) we shall use the Poincaré duality and induction isomorphisms
\[
\KK_G(B, Y) \xrightarrow{\cong} K_G(Y \times B) \xrightarrow{\cong} K_T(Y)
\]
of (23) and (36). Of course we shall set \( Y \) equal to the flag variety. Under Poincaré duality the left-hand side of (50) maps to
\[
1_B \otimes \left[ \leftarrow B \times B \right] \otimes \left[ B \times B \rightarrow pt \times B \right] \\
\otimes \left[ pt \times B \leftarrow B \times B \right] \otimes \left[ \wedge^* T^* B \boxtimes 1_B \right] \in \KK(G(B \times B)). \tag{51} \]
The composition \( B \rightarrow B \times B \rightarrow pt \times B \) is the canonical isomorphism, and so
\[
1_B \otimes \left[ \leftarrow B \times B \right] \otimes \left[ B \times B \rightarrow pt \times B \right] = 1_{pt \times B} \in \KK_G(pt \times B).
\]
It follows that (51) is simply
\[
\wedge^* T^* B \boxtimes 1_B \in \KK_G(B \times B),
\]
which corresponds under the induction isomorphism to \( \wedge^* T^* B \in \KK_T(B) \). Because of (44), this is equal to
\[
1_F \otimes \left[ F \rightarrow B \right] \in \KK_T(B),
\]
or in other words
\[
\sum_{w \in W} 1_{pt} \otimes [pt \xrightarrow{w} B],
\]
where image of the map labeled \( w \) is \( pt \cdot w \in B \). The individual terms in this sum are precisely the images of the intertwiners under the combined Poincaré duality and induction isomorphisms. \( \square \)
3.4 Comparison with Weyl’s Formula

To interpret Theorem 3.2 in representation-theoretic terms we need the vocabulary of roots and weights. Here is a quick review.

**Definition 3.3.** Let \( g \) be the complexified Lie algebra of \( G \). The flag variety \( \mathcal{B} \) is the space of Borel subalgebras of \( g \).

See for example [CG97, Chap. 3]. The flag variety is a nonsingular projective algebraic variety, and in particular a closed complex manifold. The compact group \( G \) acts transitively on \( \mathcal{B} \) and the stabilizer of any point in \( \mathcal{B} \) is a maximal torus \( T \subseteq G \). So the choice of a \( T \)-fixed base-point in \( \mathcal{B} \) identifies the flag variety with the homogeneous space \( G/T \).

**Remark 3.4.** These identifications of \( G/T \) with \( \mathcal{B} \) yield all the \( G \)-equivariant complex structures on \( G/T \), although there are other \( G \)-equivariant almost-complex structures.

Fix a base-point in \( \mathcal{B} \), that is to say a Borel subalgebra \( b \subseteq g \), and let \( T \subseteq G \) be the maximal torus that fixes \( b \). Then \( b = \mathfrak{h} \oplus \mathfrak{n} \), where \( \mathfrak{h} \) is the complexification of the Lie algebra of \( T \) and \( \mathfrak{n} = [b, b] \). Moreover

\[
g = \mathfrak{h} \oplus \mathfrak{h} \oplus \mathfrak{n}.
\]

The vector space \( \mathfrak{n} \), which is a representation of \( T \), decomposes into \( T \)-eigenspaces, each of dimension one. The corresponding eigenvalues are characters of \( T \) and may be written in the form

\[
e(\alpha): \exp(v) \mapsto \exp(\alpha(v)),
\]  

where \( v \) is in the Lie algebra of \( T \) and the complex-linear forms \( \alpha \in \mathfrak{h}^* \) are by definition the **positive roots** of \( G \) (with respect to the given choice of \( b \); our conventions follow, for example, the book of Chriss and Ginzburg [CG97, Section 3.1]).

Under the isomorphism \( K_G(\mathcal{B}) \cong K_T(pt) \) given by restriction to the base-point, the K-theory class of the bundle \( \wedge^* T^* X \) maps to

\[
A = \prod_{\alpha > 0} (1 - e(-\alpha)),
\]

where the product is over the positive roots (we are writing elements of \( K_T(pt) \) as characters, that is to say as functions on \( T \)). This is because the tangent space to \( \mathcal{B} \) at the base-point identifies with \( \mathfrak{n} \), and hence the dual vector space identifies with \( \mathfrak{n} \) as a representation of \( T \).

The positive roots are examples of **integral weights**, meaning elements of \( \mathfrak{h}^* \) that exponentiate, as in (52), to characters of \( T \). The group \( W \cong N(T)/T \) acts via the adjoint representation on the set of all integral weights. The positive
roots determine a partial order on this set, and in each \( W \)-orbit there is a maximum element, called a \textit{dominant integral weight}.

Now
\[
w(A) = e(w^{-1}(\rho) - \rho) \cdot A,
\]
for all \( w \in W \), where as usual
\[
\rho = \frac{1}{2} \sum_{\alpha > 0} \alpha \in h^*.
\]

On the basis of (53) we find that the intertwining operators \( I_w \) act as follows on \( K_G(\mathcal{B}) \cong K_T(pt) \):
\[
e(\psi) \otimes I_w = (-1)^w e(w^{-1}(\psi + \rho) - \rho) \in K_T(pt),
\]
where the sign is the determinant of \( w \) as it acts on the Lie algebra of \( T \).

\textbf{Remark 3.5.} Using these things we can complete some unfinished business. We want to show that
\[
[pt \leftarrow \mathcal{B}] \otimes [\mathcal{B} \rightarrow pt] = \text{Id}_{pt} \in \mathbb{K}K_G(pt, pt)
\]
as in (39). To calculate the left-hand side we can restrict to \( T \) since restriction here is injective; call the result \( \Phi \in \mathbb{K}K_T(pt, pt) \). According to Theorem 3.2,
\[
\Phi \cdot \prod_{\alpha > 0} (1 - e(-\alpha)) = \sum (-1)^w e(w(\rho) - \rho).
\]
Comparing the two sides, we see that the only dominant weight occurring in \( \Phi \) is the trivial weight. Since the weights of \( \Phi \) are acted on by \( W \), the only weight of \( \Phi \) is the trivial weight, and it occurs with multiplicity one. Hence \( \Phi \) is the trivial representation, as required. See [Ati68] for a different, geometric approach.

\textbf{Remark 3.6.} Let \( V \) be a finite-dimensional representation of \( G \). The localization map associates to \( V \) (the K-theory class of) the complex of vector bundles
\[
\wedge^0 n \otimes V \leftarrow \wedge^1 n \otimes V \leftarrow \cdots
\]
that fiberwise computes nilpotent Lie algebra homology (here \( d = \dim(n) \), or in other words the number of positive roots). So the localization map could equally well be defined to map \( V \) to the alternating sum of the bundles whose fibers are the homology spaces \( H_\rho(n, V) \). The connection between the Weyl character formula and nilpotent Lie algebra homology was thoroughly explored by Kostant in [Kos61].

By now we have encountered all the ingredients of Weyl’s formula:
Theorem 3.7 (Weyl Character Formula). There is a bijection between equivalence classes of irreducible finite-dimensional representations of $G$ under which the character of the representation associated to a dominant integral weights $\psi$ is equal to

$$\sum_{w \in W} (-1)^w e(w(\psi + \rho) - \rho) \prod_{\alpha > 0} (1 - e(-\alpha))$$

on $T$ (the product is over the positive roots). The highest weight of the representation is $\psi$.

Let us write

$$\Lambda: K_G(pt) \to K_G(\mathcal{B})$$

for the map induced by pullback from a point, followed by multiplication against $\wedge^* T^* \mathcal{B} \in K_G(\mathcal{B})$, and

$$\Gamma: K_G(\mathcal{B}) \to K_G(pt)$$

for the wrong-way map induced from the collapse of $\mathcal{B}$ to a point. Theorem 3.2 asserts that

$$\Lambda \circ \Gamma = \sum_{I_w} I_w: K_G(\mathcal{B}) \to K_G(\mathcal{B})$$

and

$$\Gamma \circ \Lambda = |W| \cdot \text{Id}: K_G(pt) \to K_G(pt).$$

According to equation (57), if $\psi$ is any integral weight, then the character of the virtual representation $V_\psi = \Gamma(e(\psi)) \in K_G(pt)$ is given by Weyl’s formula, and it follows from the formula that if $\psi$ is dominant, then the highest weight of the representation is $\psi$. The rest of the content of Theorem 3.7, that these virtual representations are actually irreducible representations, and that they are all of them, requires a bit more effort, going beyond K-theory and our concerns here.\footnote{A more thorough analysis of the combinatorial relations between the Weyl group and the positive roots shows that the virtual representations $V_\psi$ associated to dominant weights form a basis for $K_G(pt)$. Meanwhile the Weyl integral formula implies that $\Gamma$ and $\Lambda$ are adjoint with respect to the natural inner products on $K_G(pt)$ and $K_G(\mathcal{B}) \cong K_T(pt)$ for which the irreducible representations are orthonormal:

$$\langle x, \Gamma(z) \rangle_G = \langle \Lambda(x), z \rangle_T$$

From this it follows easily that $\Gamma$ maps dominant integral weights to irreducible representations.}
3.5 A Second Look at KK-Theory for the Flag Variety

We shall continue to borrow from Lie theory and sketch a calculation of the ring $\mathbb{KK}_G(B, B)$ (which we shall not use later). In view of the Poincaré duality isomorphism, this is effectively a problem in equivariant topological K-theory, and indeed it is one that has been addressed and solved in this guise (for example the discussion here closely parallels [HLS10] in many places).

Let $\alpha$ be a simple positive root. Associated to it there is a generalized flag variety $B_\alpha$ consisting of all subalgebras $p \subseteq g$ conjugate to $p_\alpha = n_\alpha \oplus n$, where $n_\alpha$ is the $\alpha$-root space in $n$. There is a $G$-equivariant submersion $B \rightarrow B_\alpha$ given by inclusion of subalgebras $b \subseteq p$. Define

$$\Pi_\alpha = [\mathcal{B} \rightarrow B_\alpha] \otimes [B_\alpha \leftarrow \mathcal{B}] \in \mathbb{KK}_G(B, B).$$  \hspace{1cm} (59)  

**Proposition 3.8.** If $\alpha$ is any simple root, then

$$\Pi_\alpha \otimes \Pi_\alpha = \Pi_\alpha \in \mathbb{KK}_G(B, B).$$

**Proof.** We want to show that

$$[\mathcal{B} \rightarrow B_\alpha] \otimes [B_\alpha \leftarrow \mathcal{B}] \otimes [B \rightarrow B_\alpha] \otimes [B_\alpha \leftarrow \mathcal{B}] = [\mathcal{B} \rightarrow B_\alpha] \otimes [B_\alpha \leftarrow \mathcal{B}],$$

and so of course it suffices to show that

$$[B_\alpha \leftarrow \mathcal{B}] \otimes [\mathcal{B} \rightarrow B_\alpha] = \text{Id}_{B_\alpha} \in \mathbb{KK}_G(B_\alpha, B_\alpha).$$ \hspace{1cm} (60)  \hspace{1cm} \text{eq-bs-project}

But if $G_\alpha \subseteq G$ is the stabilizer of the base-point in $B_\alpha$, then $\mathcal{B} \cong \text{Ind}_{G_\alpha}^G G_\alpha / T$, and (60) follows from the identity

$$[\text{pt} \rightarrow G_\alpha / T] \otimes [G_\alpha / T \rightarrow \text{pt}] = \text{Id}_{\text{pt}} \in \mathbb{KK}_{G_\alpha}(\text{pt}, \text{pt})$$

using the induction homomorphism (34). The latter identity is Atiyah's formula (39) for the group $G_\alpha$. \hfill \Box

The idempotents $\Pi_\alpha$ are related to intertwiners, as follows:

**Proposition 3.9.** If $\alpha$ is a simple root, then

$$\Pi_\alpha \otimes [1 - e(-\alpha)] = \text{Id}_B + I_{s_\alpha} \in \mathbb{KK}_G(B, B),$$

where $s_\alpha \in W$ is the reflection associated to $\alpha$.

**Proof.** If $G = G_\alpha$, then this is the Weyl character formula. The general case follows by induction from $G_\alpha$ to $G$ as above. \hfill \Box
The $\Pi_\alpha$, at least when considered as operators on $K_G(B)$ by Kasparov product, are called Demazure operators. Compare [Dem74, Sec. 1] or [HLS10, Sec. 1]. From the proposition we obtain the following formula for the action of $\Pi_\alpha$ on $K_G(B)$:

$$e(\phi) \otimes \Pi_\alpha = \frac{e(\phi) - e(-\alpha)e(s_\alpha(\phi))}{1 - e(-\alpha)} \in K_G(B).$$  \hspace{0.6em} (61) eq-div-diff-ops1

In addition the commutation relations in $KK_G(B,B)$ between the elements $\Pi_\alpha$ and elements of the subring $K_G(B) \subseteq KK_G(B,B)$ are as follows:

$$[e(\phi)] \otimes \Pi_\alpha = \frac{e(\phi) - e(s_\alpha(\phi))}{1 - e(-\alpha)} + \Pi_\alpha \otimes [e(s_\alpha(\phi))] \in KK_G(B,B).$$  \hspace{0.6em} (62) eq-div-diff-ops2

Remark 3.10. In the reverse direction, Proposition 3.9 gives a new formula for the intertwining operators. It is of some interest because its constituent parts are maps and bundles that are holomorphic and equivariant for the full group of symmetries of $B$, namely the complexification $G_C$ of $G$ (in contrast to the $G$-equivariant maps from $B$ to itself that we considered in Section 3.2).

Another approach to intertwiners uses the Bruhat cells in $B \times B$. These are the $G_C$-orbits, and each one contains the graph of a unique $G$-equivariant map from $B$ to itself. So we may label them as

$$C^w \subseteq B \times B,$$  \hspace{0.6em} (63) eq-bruhat

where $w \in W$. The $K_G$-theory wrong-way maps associated to the two coordinate projections from $C^w$ to $B$ are isomorphisms. Indeed both projections give $C^w$ the structure of a complex $G$-equivariant vector bundle (the zero section is the graph of $w$), and so the Thom isomorphism theorem applies. Composing one with the inverse of the other gives an intertwined. The commuting diagram

$$\begin{array}{ccc}
C^w & \xleftarrow{w} & B \\
\downarrow & & \downarrow \\
B & \xrightarrow{w} & B,
\end{array}$$

where the left and right downwards maps are the left and right projections, shows that the intertwiner defined this way is the same as ours. Compare [EY09].

Returning to the idempotents $\Pi_\alpha$, we next consider how the idempotents associated to two distinct simple roots interact.

**Proposition 3.11 (Demazure [Dem74]).** The operators $\Pi_\alpha \in KK_G(B,B)$ associated to simple roots satisfy the braid relations.

**Proof.** The braid relations may be checked by computation using Proposition 3.9 (although as Demazure writes, the calculation “est clair si $m = 2$, facile pour $m = 3$, faisable pour $m = 4$ et épouvantable pour $m = 6$”). See also [BE92, Gut88] for some improvements on the brute force approach. □
Proposition 3.12. Let $\alpha_1, \ldots, \alpha_n$ be a reduced list of simple roots. The class

$$\Pi_{\alpha_1} \otimes \cdots \otimes \Pi_{\alpha_n} \in \mathbb{K}K_G(\mathcal{B}, \mathcal{B})$$  \hfill (64)

depends only on the element $w = s_{\alpha_1} \cdots s_{\alpha_n} \in W$. The subring of $\mathbb{K}K_G(\mathcal{B}, \mathcal{B})$ generated by the elements $\Pi_{\alpha_i}$ associated to simple roots is the universal ring generated by idempotents $\Pi_{\alpha_i}$ subject only to the braid relations, and it is spanned over $\mathbb{Z}$ by the elements (64).

Proof. See [Bou02, Chap 4, Sec 1, Prop 5]. \qed

Definition 3.13. If $w \in W$, then denote by $\Pi_w \in \mathbb{K}K_G(\mathcal{B}, \mathcal{B})$ the Kasparov product (64).

These elements constitute a basis for $\mathbb{K}K_G(\mathcal{B}, \mathcal{B})$ (as either a left or right module over $K_G(\mathcal{B})$). We can see this by making use of the following additional geometric ideas.

Definition 3.14. Let $\alpha = (\alpha_1, \ldots, \alpha_n)$ be an ordered list of simple roots (with repetitions or reoccurrences allowed). Define

$$\mathcal{B}S^\alpha = \{ (w_0, \ldots, w_n) \in \mathcal{B} \times \cdots \times \mathcal{B} : \pi_{\alpha_k}(w_{k-1}) = \pi_{\alpha_k}(w_k) \ \forall k \}.$$  \hfill (65)

In addition, denote by

$$p_0, p_n : \mathcal{B}S^\alpha \longrightarrow \mathcal{B}$$

the projections onto the $w_0$- and $w_n$-coordinates.

Remark 3.15. The Bott-Samelson variety $\mathcal{B}S^\alpha_{pt}$ associated to the list of simple roots $\alpha = (\alpha_1, \ldots, \alpha_n)$ and to a given basepoint $pt \in \mathcal{B}$ is the inverse image of the basepoint under $p_n$; see [BS58, Han73]. This explains the notation.

Definition 3.16. Let $\alpha = (\alpha_1, \ldots, \alpha_n)$ be any ordered list of simple roots. Denote by $\Pi_{\alpha_1, \ldots, \alpha_n} \in \mathbb{K}K_G(\mathcal{B}, \mathcal{B})$ the Kasparov product

$$[\mathcal{B} \overset{p_0}{\longleftarrow} \mathcal{B}S^\alpha] \otimes [\mathcal{B}S^\alpha \overset{p_n}{\longrightarrow} \mathcal{B}].$$

Example 3.17. If the list has length one, then the new definition of $\Pi_{\alpha}$ agrees with the old one in view of the pullback diagram

$$\begin{array}{ccc}
\mathcal{B}S^\alpha & \overset{p_n}{\longrightarrow} & \mathcal{B} \\
| & | & | \\
p_0 & \downarrow & \downarrow \\
\mathcal{B} & \longrightarrow & \mathcal{B}_n
\end{array}$$

and Lemma 2.14.

Lemma 3.18. If $\alpha_1, \ldots, \alpha_n$ is any list of simple roots, then

$$\Pi_{\alpha_1, \ldots, \alpha_n} = \Pi_{\alpha_1} \otimes \cdots \otimes \Pi_{\alpha_n} \in \mathbb{K}K_G(\mathcal{B}, \mathcal{B}).$$
Proof. This follows by repeated application of the base-change formula in Lemma 2.14. 

Now, fixing a base-point, as usual, denote by \( C^w_{pt} \subseteq B \) the image under the left-projection to \( B \) of the inverse image of \( pt \in B \) under the right-hand projection of the Bruhat cell \( C^w \) to \( B \). The \( C^w_{pt} \) are the Bruhat cells in \( B \). They are affine \( T \)-spaces (of dimension equal to the length of \( w \)), they are pairwise disjoint, their union is \( B \), and the closure of each \( C^w_{pt} \) is contained in the union of cells of lower dimension. This is the Bruhat decomposition, and follows from it that:

**Lemma 3.19.** The group \( \mathbb{K} \mathbb{K}_G(B, B) \) is a free right and left module of rank \( |W| \) over the commutative ring \( K_G(B) \). 

**Lemma 3.20.** The elements \( \Pi_w \in \mathbb{K} \mathbb{K}_G(B, B) \) freely generate \( \mathbb{K} \mathbb{K}_G(B, B) \) as a right or left \( K_G(B) \)-module, as \( w \) ranges over the Weyl group.

Proof. Let us consider the left-module result; the right module result is similar and in any case it can be deduced from the left module result by means of (62). Let \( w \in W \), let

\[
w = s_{\alpha_1} \cdots s_{\alpha_n}
\]

be a factorization of \( w \) as a minimal-length product of simple reflections and let \( \alpha = (\alpha_1, \ldots, \alpha_n) \). Under the induction/restriction isomorphism

\[
\mathbb{K} \mathbb{K}_G(B, B) \xrightarrow{\sim} \mathbb{K} \mathbb{K}_T(B, pt)
\]

the element \( \Pi^w = \Pi^\alpha \) maps to

\[
[B \leftarrow BS^\alpha_{pt}] \otimes [BS^\alpha_{pt} \rightarrow pt]
\]

Now the image of \( BS^\alpha_{pt} \) in \( B \) is the closure of the Bruhat cell \( C^w_{pt} \) (see [Han73]), so the class (66) actually lies in the image of

\[
\mathbb{K} \mathbb{K}_T(C^w_{pt}, pt) \longrightarrow \mathbb{K} \mathbb{K}_T(B, pt)
\]

Moreover the projection from the inverse image of \( C^w_{pt} \) in \( BS^\alpha_{pt} \) back down to \( C^w_{pt} \) is an isomorphism (see [Han73] again). So under

\[
\mathbb{K} \mathbb{K}_T(C^w_{pt}, pt) \longrightarrow \mathbb{K} \mathbb{K}_T(C^w_{pt}, pt)
\]

the class (66) is mapped to a generator. The lemma follows from this and the Bruhat decomposition. 

Finally, let us mention Demazure’s character formula [Dem74, RR85, And85] and its relation to the problem of computing the restriction map in equivariant K-theory.
Theorem 3.21. If $\Pi \in KK_G(\mathcal{B}, \mathcal{B})$ is the class $[\mathcal{B} \to \text{pt}] \otimes [\text{pt} \leftarrow \mathcal{B}]$ from (40), then

$$\Pi = \Pi_{\alpha_1, \ldots, \alpha_n} = \Pi_{\alpha_1} \otimes \cdots \otimes \Pi_{\alpha_n} \in KK_G(\mathcal{B}, \mathcal{B}),$$

where $\alpha_1, \ldots, \alpha_n$ is any list of simple roots for which the associated product of simple reflections is the longest element of the Weyl group.

As pointed out in [HLS10], Demazure’s formula gives a characterization of the range of the restriction map

$$K_G(Z) \to K_T(Z),$$

or equivalently of the range of the pullback map

$$K_G(Z) \to K_G(\mathcal{B} \times Z). \tag{67}$$

Lemma 3.22. The right ideal in $KK_G(\mathcal{B}, \mathcal{B})$ generated by the $\text{Id} - \Pi_{\alpha}$ as $\alpha$ ranges over the simple roots is equal to the right ideal generated by $\text{Id} - \Pi$.

Proof. If $\alpha_1, \ldots, \alpha_k$ is any list of simple roots (of any length), then

$$\text{Id} - \Pi_{\alpha_1, \ldots, \alpha_k} = (\text{Id} - \Pi_{\alpha_k}) + (\text{Id} - \Pi_{\alpha_1, \ldots, \alpha_{k-1}}) \otimes \Pi_{\alpha_k}$$

and so by an induction argument $\text{Id} - \Pi_{\alpha_1, \ldots, \alpha_k}$ is in the right-ideal of $KK_G(\mathcal{B}, \mathcal{B})$ generated by the $\text{Id} - \Pi_{\alpha}$. In particular, $\text{Id} - \Pi$ lies in this ideal.

Conversely, we have

$$\text{Id} - \Pi_{\alpha} = (\text{Id} - \Pi) - (\text{Id} - \Pi) \Pi_{\alpha_n}$$

since $\Pi_{\alpha_n}$ is an idempotent. But any simple root $\alpha$ can play the role of $\alpha_n$ in the formula for $\Pi$ (that is, it can appear last in some reduced expression for the longest word in $W$). We find therefore that if $\alpha$ is any simple root then $\text{Id} - \Pi_{\alpha}$ lies in the right ideal generated by $\text{Id} - \Pi$. \qed

The range of (67) is equal to the range of the continuous transformation

$$\Pi : K_G(\mathcal{B} \times Z) \to K_G(\mathcal{B} \times Z),$$

and since $\Pi$ is an idempotent, this is the same as the kernel of $\text{Id} - \Pi$. The lemma implies that this is the same as the joint kernel of the operators $\text{Id} - \Pi_{\alpha}$.

See also [Leu11], where the argument of [HLS10] is also considered within the context of KK-theory, although not as we did above.

4 The Baum-Connes Conjecture

In this final section we shall examine the Baum-Connes conjecture [BCH94] for connected Lie groups in the light of the previous calculations.
4.1 Equivariant K-Theory for Noncompact Groups

Let $G$ be a locally compact Hausdorff topological group and let $X$ be a locally compact Hausdorff space equipped with a continuous action of $G$. There is more than one plausible definition of the $G$-equivariant $K$-theory of $X$. We shall use the definition that is most closely related to the Baum-Connes conjecture. It requires a certain amount of functional and harmonic analysis.

Fix a left Haar measure on $G$. The reduced $C^*$-algebra of $G$, denoted here $C^*_{\text{red}}(G)$, is the completion in the operator norm of the convolution algebra of continuous, compactly supported functions on $G$ as it acts on the Hilbert space $L^2(G)$. See for example [Ped79]. One reason for preferring this particular Banach algebra completion is its close connection to Fourier theory: if $G$ is abelian, then $C^*_{\text{red}}(G)$ is isometrically isomorphic via the Fourier transform to the algebra of continuous complex functions, vanishing at infinity, on the Pontrjagin dual of $G$. Thus $C^*_{\text{red}}(G)$ is relevant to problems where the topology of the dual space is important.

For nonamenable groups, $C^*_{\text{red}}(G)$ reflects topological features of the reduced unitary dual. For reductive Lie groups this is the support of the Plancherel measure, or in other words the tempered unitary dual.

If $A$ is any $C^*$-algebra that is equipped with a continuous action of $G$ by $C^*$-algebra automorphisms, then the reduced crossed product algebra $C^*_{\text{red}}(G,A)$ is similarly a completion of the twisted convolution algebra of compactly supported and continuous functions from $G$ into $A$. The convolution product is

$$f_1 \star f_2(g) = \int_G f_1(h)\alpha(h)(f_2(h^{-1}g)) \, dh,$$

where $\alpha$ denotes the action of $G$ on $A$. If $A$ is represented faithfully and isometrically on a Hilbert space $H$, then $C^*_{\text{red}}(G,A)$ is represented faithfully and isometrically on the Hilbert space completion $L^2(G,H)$ of the continuous and compactly supported functions from $G$ into $H$. See [Ped79] again.

We define the equivariant K-theory of $A$ to be the $K$-theory of the reduced crossed product algebra:

$$K_G(A) = K(C^*_{\text{red}}(G,A)), \tag{68}$$

and if $X$ is a locally compact $G$-space, then we define the equivariant K-theory of $X$ to be the $K$-theory of the reduced crossed product algebra in the case $A = C_0(X)$:

$$K_G(X) = K(C^*_{\text{red}}(G,C_0(X))). \tag{69}$$

The definition is arranged so that $K_G(\text{pt}) = K(C^*_{\text{red}}(G))$. As we noted, this $K$-theory group should reflect aspects of the topology of the tempered dual,\textsuperscript{6}

\textsuperscript{6} The exemplar is the discrete series, which appear as isolated points in the tempered dual and are reflected simply and clearly in the K-theory. See the introduction.
and the aim of the Baum-Connes theory is to use geometric techniques to understand these aspects more fully.

Unfortunately in most cases it is not easy to give a geometric description of cycles and generators for equivariant K-theory akin to the standard vector bundle description of K-theory in the case of compact groups. Because of this it is considerably more difficult to define geometric operations on K-theory groups (such as wrong-way maps, and so on) in the noncompact case. It is here that Kasparov’s equivariant KK-theory plays a crucial role, providing by means of functional-analytic constructions some operations in some circumstances. We shall invoke it in some very simple situations. As we shall see, the Baum-Connes conjecture asserts that a full suite of operations can be indeed be obtained by reduction to the case of compact groups, but of course it is at the moment still a conjecture.

The equivariant K-theory group $K_G(X)$ that we have defined is not in general a ring. It is however a module over the Grothendieck ring $K_{vb}G(X)$ of $G$-equivariant Hermitian vector bundles on $X$. In terms of Kasparov’s analytic theory this may be explained as follows. Kasparov defines a product

$$K_G(X) \otimes KK_G(X, X) \to K_G(X)$$

(70) \hspace{1cm} \text{eq-kk-action}

in [Kas88, Sec 3.11]. Note that this involves Kasparov’s functional-analytic KK-theory, not ours. Meanwhile there is a ring homomorphism

$$K_{vb}G(X) \to KK_G(X, X).$$

(71) \hspace{1cm} \text{eq-kasp-kk-classes}

It is a counterpart of the one defined in (13). The combination of (70) and (71) gives our the required module action

$$K_G(X) \otimes K_{vb}G(X) \to K_G(X).$$

(72) \hspace{1cm} \text{eq-vb-action}

There is a modest but nonetheless very important extension of (72). Suppose given a bounded and compactly supported complex of equivariant hermitian vector bundles

$$E_0 \leftarrow E_1 \leftarrow \cdots \leftarrow E_k$$

(73) \hspace{1cm} \text{eq-almost-eq-cplx}

over a locally compact space $X$, as in (3), except that we do not require the differentials to be $G$-equivariant. Instead we require that the conjugate of a differential by an element $g \in G$ differs from the differential by a bundle homomorphism that vanishes at infinity on $W$ (and varies continuously with $g$). Each such almost equivariant Hermitian complex also determines a class in Kasparov’s $KK_G(X, X)$, and so acts as an operator on $K_G(X)$.

Suppose now that $H$ is a closed subgroup of $G$. There is in general no restriction homomorphism from $G$-equivariant to $H$-equivariant K-theory as there was in the compact case, but there is however an induction isomorphism

$$K_G(\text{Ind}_H^G X) \cong K_H(X)$$

(74)
exactly analogous to (30). This follows from the fact that $C^*_{\text{red}}(G, \text{Ind}_H^G X)$ and $C^*_{\text{red}}(H, X)$ are in a canonical way Morita equivalent $C^*$-algebras. More generally, if a locally compact space $W$ admits commuting free and proper actions of two locally compact groups $H$ and $G$, then there is a Morita equivalence between crossed product algebras

$$C^*_{\text{red}}(G, W/H) \quad \text{and} \quad C^*_{\text{red}}(H, W/G)$$

See [Rie82]. This leads to a K-theory isomorphism

$$K_G(W/H) \cong K_H(W/G).$$

In the present case, we may apply this to $W = G \times X$.

Finally, although equivariant K-theory as we have defined it in this section is in general rather complicated, in the case of a compact group it reduces to the usual equivariant K-theory that we considered earlier in the paper. This is the content of the Green-Julg theorem [Gre82, Jul81].

### 4.2 Equivariant KK-Theory for Noncompact Groups

We have made use of Kasparov’s KK-theory in the previous section, although only as a shortcut to defining the action of hermitian equivariant vector bundles, or almost equivariant complexes of hermitian equivariant vector bundles, on our $C^*$-algebraic equivariant K-theory. Now we shall define a version of the $KK$-theory that we considered for compact groups earlier in the paper.

**Definition 4.1.** Denote by $KK_G(X, Y)$ the abelian group of all natural transformations

$$T_Z : K_G(X \times Z) \rightarrow K_G(Y \times Z)$$

with the property that diagrams of the form

$$\begin{array}{ccc}
K_G(X \times Z) & \xrightarrow{T_Z} & K_G(Y \times Z) \\
\downarrow & & \downarrow \\
K_G(X \times Z \times W) & \xrightarrow{T_{Z \times W}} & K_G(Y \times Z \times W),
\end{array}$$

in with the vertical maps are multiplication by some equivariant Hermitian vector bundle or almost-equivariant complexes of Hermitian vector bundles on $W$, all commute.

---

7 The cited paper deals with maximal crossed product algebras rather than the reduced crossed product algebras that we are considering here. However we shall only use the theorem in situations where the two types of crossed products agree.
Remark 4.2. Of course if $G$ is compact then this is the very same theory that we considered earlier, and hence it matches closely with Kasparov’s theory as described in Section 2.7. In the noncompact case the difference between $\mathbb{K}K_G(X,Y)$ and $KK_G(X,Y)$ is usually quite a bit greater. There is a natural map
\[ KK_G(X,Y) \to KK_G(X,Y) \]
that is compatible with Kasparov products and actions on equivariant K-theory, but unfortunately it is frequently not an isomorphism. This points to the difficulty of using Kasparov’s concretely defined equivariant KK-theory groups in computations of equivariant K-theory, since it can and does happen that the action of a $KK_G$-class on $K_G$-groups is an isomorphism, whereas the class is not itself an isomorphism in $KK_G$-theory. (On the other hand $KK_G$-theory is defined directly in terms of equivariant K$_G$-theory, but its abstract definition reduces its value as a computational tool.)

4.3 Reformulation of the Baum-Connes Conjecture

From now on assume that $G$ is a connected Lie group. It contains a maximal compact subgroup $K$, and $K$ is unique up to conjugacy [Bor98, Chapter VII]. Form the “symmetric space” $S = G/K$ (we’re interested in the case where $G$ is a reductive group, in which case $S$ really is a Riemannian symmetric space).

In what follows in the final part of this paper we shall focus on the restriction homomorphism
\[ KK_G(X,Y) \to KK_K(X,Y). \] (75)  

This is defined exactly as in (33); as noted in Remark 2.20, the definition uses only the induction isomorphism in equivariant K-theory, which is still available to us in the noncompact context, and not restriction, which isn’t.

Baum and Connes define an assembly map, involving Kasparov’s KK-theory, as follows:
\[ \mu: KK_G(S,X) \to K_G(X) \]
See [BCH94, Sec. 3] (the assembly map is in fact defined for all $G$-$C^*$-algebras $A$, but we shall keep to the main case of interest, which is $A = C_0(X)$).

Conjecture 4.3 (Baum and Connes). Let $G$ be a connected Lie group with maximal compact subgroup $K$, and let $S = G/K$. If $X$ is any locally compact $G$-space, then the assembly map
\[ \mu: KK_G(S,X) \to K_G(X) \] (76)
is an isomorphism of abelian groups.

Remark 4.4. This is what the experts would call the Baum-Connes conjecture with commutative coefficients—the coefficients being the $C^*$-algebra $C_0(X)$. The case $X = pt$ is known for all connected Lie groups; see [CEN03]. The conjecture as stated is known for a limited class of groups—among the noncompact simple Lie groups only those of rank one [Kas84, JK95, Jul02].
Now Kasparov showed that there is a Poincaré duality isomorphism

$$\text{KK}_G(S,X) \cong \text{K}_G(X \times TS),$$

and so the Baum-Connes assembly map can be viewed as a homomorphism

$$\text{K}_G(X \times TS) \longrightarrow \text{K}_G(X).$$

(77) \hspace{1cm} \text{eq-pd-form-bc}

It is implemented by a class $$D \in \text{KK}_G(TS,pt)$$, namely Kasparov’s Dirac class [Kas88, Sec. 4]. It is a remarkable feature of the Kasparov theory that there is a class $$\tilde{D} \in \text{KK}_G(pt,TS)$$, the dual Dirac class, which induces a right inverse map

$$\text{K}_G(X) \longrightarrow \text{K}_G(X \times TS)$$

(78) \hspace{1cm} \text{eq-dual-dirac-bc}

to (77); see [Kas88, Sec. 5]. Thus

$$D \otimes \tilde{D} = \text{Id}_{TS} \in \text{KK}_G(TS,TS).$$

The dual Dirac class is represented by an almost-equivariant complex of Hermitian vector bundles on $$TS$$.

**Lemma 4.5.** Conjecture 4.3 is equivalent to the assertion that the restriction map

$$R = \text{Res}_K^G: \text{KK}_G(X,Y) \longrightarrow \text{KK}_K(X,Y)$$

is an isomorphism for all locally compact $$G$$-spaces $$X$$ and $$Y$$.

**Proof.** If $$X$$ and $$Y$$ are locally compact $$G$$-spaces, and if $$T \in \text{KK}_G(X,Y)$$, then its restriction to a class $$R(T) \in \text{KK}_K(X,Y)$$ is given by the diagram

\[
\begin{array}{ccc}
K_K(X \times Z) & \xrightarrow{R(T)z} & K_K(Y \times Z) \\
\cong & & \cong \\
K_G(\text{Ind}_K^G(X \times Z)) & \cong & K_G(\text{Ind}_K^G(Y \times Z)) \\
\cong & & \cong \\
K_G(X \times \text{Ind}_K^G Z) & \xrightarrow{T_{\text{Ind}_K^G z}} & K_G(Y \times \text{Ind}_K^G Z).
\end{array}
\]

as in (33). The Baum-Connes conjecture implies that the maps (77) and (78) induced from Kasparov’s $$D \in \text{KK}_G(TS,pt)$$ and $$\tilde{D} \in \text{KK}_G(pt,TS)$$ are isomorphisms. But $$TS$$ is $$G$$-equivariantly homeomorphic to $$S \times S$$ via the exponential map, and so assuming the Baum-Connes conjecture there are isomorphisms

$$D \in \text{KK}_G(S \times S,pt) \quad \text{and} \quad \tilde{D} \in \text{KK}_G(pt,S \times S)$$

(79) \hspace{1cm} \text{eq-new-diracs}

The latter is given by an almost-equivariant complex of Hermitian vector bundles on $$S \times S$$, so its action on K-theory commutes with the action of
$\KK$-classes (in the sense of Lemma 2.10). Given these things, the inverse to the restriction map may be defined by means of the diagram

$$
\begin{array}{ccc}
\K_G(X \times Z) & \xrightarrow{R^{-1}(T)z} & \K_G(Y \times Z) \\
\cong & & \cong \\
\K_G(X \times S \times S \times Z) & \cong & \K_G(Y \times S \times S \times Z) \\
\cong & & \cong \\
\K_K(X \times S \times Z) & \xrightarrow{T_{S \times Z}} & \K_K(X \times S \times Z)
\end{array}
$$

where the top vertical maps are induced from the class $D^\ast$ in (79).

Conversely, assume the restriction map is an isomorphism. The restrictions of $D$ and $D^\ast$ to $K$-equivariant Kasparov theory are isomorphisms, and hence they are isomorphisms in $K$-equivariant $\KK$-theory. By our assumption they are isomorphisms in $G$-equivariant $\KK$-theory too, which proves that the Baum-Connes assembly map in the form (77) is an isomorphism. \hfill \Box

### 4.4 Baum-Connes and the Flag Variety

Throughout this section let $G \subseteq GL(n, \mathbb{R})$ be a linear connected real reductive Lie group, let $\mathfrak{g}$ be its complexified Lie algebra and let $B$ be the flag variety associated to $\mathfrak{g}$. Let $K$ be a maximal compact subgroup in $G$.

There is a compact form $G_{\text{comp}}$ of $G$ (that is, a compact connected subgroup of $GL(n, \mathbb{C})$ with the same complexified Lie algebra $\mathfrak{g}$) and we may choose it to contain $K$. Formulate the Weyl character formula for $G_{\text{comp}}$ in equivariant $\KK$-theory, as in Theorem 3.2. We obtain identities (49) and (50) in $\KK_{G_{\text{comp}}}$-theory, but using the restriction functor (31) from $G_{\text{comp}}$-equivariant $\KK$-theory to $K$-equivariant $\KK$-theory we obtain the formulas

$$\left[ \text{pt} \leftarrow \mathcal{B} \right] \otimes \left[ \wedge^* T^* \mathcal{B} \right] \otimes \left[ \mathcal{B} \rightarrow \text{pt} \right] = |W| : [\text{pt} \rightarrow \text{pt}] \in \KK_K(\text{pt}, \text{pt})$$

and

$$\left[ \mathcal{B} \rightarrow \text{pt} \right] \otimes \left[ \text{pt} \leftarrow \mathcal{B} \right] \otimes \left[ \wedge^* T^* \mathcal{B} \right] = \sum_{w \in W} \left[ \mathcal{B} \xrightarrow{w} \mathcal{B} \right] \in \KK_K(\mathcal{B}, \mathcal{B}).$$

Here $\mathcal{B}$ continues to be the flag variety for $\mathfrak{g}$ and $W$ is the Weyl group for $\mathfrak{g}$ (not the compact group $K$).

If we assume the Baum-Connes conjecture, then by inverting the restriction functor

$$\text{Res}_{K}^G : \KK_K(X, Y) \longrightarrow \KK_K(X, Y)$$

we obtain classes $[\mathcal{B} \rightarrow \text{pt}]$ and so on in $G$-equivariant $\KK$-theory, and the same identities among them as above. In other words, we obtain a $\KK$-theoretic Weyl character formula for the noncompact group $G$. 

Using the notation introduced in Section 3.4, we obtain “global sections” and “localization” maps
\[ \Gamma : K_G(\mathcal{B} \times X) \to K_G(X) \quad \text{and} \quad \Lambda : K_G(X) \to K_G(\mathcal{B} \times X), \]
as well as “intertwining operators”
\[ I_w : K_G(\mathcal{B} \times X) \to K_G(\mathcal{B} \times X) \]
with
\[ \Lambda \otimes \Gamma = |W| \cdot \text{Id} : K_G(X) \to K_G(X) \]
and
\[ \Gamma \otimes \Lambda = \sum_{w \in W} I_w : K_G(\mathcal{B} \times X) \to K_G(\mathcal{B} \times X). \]

After inverting $|W|$ the formulas identity $K_G(X)$ with the $W$-invariant part for $K_G(\mathcal{B} \times X)$. A more precise (but maybe less useful) statement can be obtained using the Demazure character formula, as in Section 3.5.
