Vector Differential Equations: Nondefective Coefficient Matrix

Math 240 — Calculus III

Summer 2013, Session II

Tuesday, July 30, 2013
1. Solving linear systems by diagonalization
   Real eigenvalues
   Complex eigenvalues
The results discussed yesterday apply to any old vector differential equation

\[ x' = Ax. \]

In order to make some headway in solving them, however, we must make a simplifying assumption:

The coefficient matrix \( A \) consists of real constants.
Recall that an $n \times n$ matrix $A$ may be diagonalized if and only if it is nondefective.

When this happens, we can solve the homogeneous vector differential equation
\[ x' = Ax. \]

If $S^{-1}AS = \text{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n)$, then
\[ x = Sy, \text{ where } y = \begin{bmatrix} c_1e^{\lambda_1t} \\ c_2e^{\lambda_2t} \\ \vdots \\ c_ne^{\lambda_nt} \end{bmatrix}. \]
Example

Solve the linear system

\[
\begin{align*}
x_1' &= 2x_1 + x_2, \\
x_2' &= -3x_1 - 2x_2.
\end{align*}
\]

1. Turn it into the vector differential equation

\[
x' = Ax,
\]

where

\[
A = \begin{bmatrix}
2 & 1 \\
-3 & -2
\end{bmatrix}.
\]

2. The characteristic polynomial of \(A\) is \(\lambda^2 - 1\).

3. Eigenvalues are \(\lambda = \pm 1\).

4. Eigenvectors are

\[
\begin{align*}
\lambda_1 = 1 : & \quad v_1 = (-1, 1), \\
\lambda_2 = -1 : & \quad v_2 = (-1, 3).
\end{align*}
\]

5. We have

\[
y = \begin{bmatrix}
c_1 e^t \\
c_2 e^{-t}
\end{bmatrix}, \text{ so } x = \begin{bmatrix}
-1 & -1 \\
1 & 3
\end{bmatrix} y = \begin{bmatrix}
-c_1 e^t - c_2 e^{-t} \\
c_1 e^t + 3c_2 e^{-t}
\end{bmatrix}.
\]
The change of basis matrix $S$ is

$$S = \begin{bmatrix} \mathbf{v}_1 & \mathbf{v}_2 & \cdots & \mathbf{v}_n \end{bmatrix},$$

where $\mathbf{v}_1, \ldots, \mathbf{v}_n$ are $n$ linearly independent eigenvectors of $A$. Hence,

$$\mathbf{x} = S \mathbf{y} = c_1 e^{\lambda_1 t} \mathbf{v}_1 + c_2 e^{\lambda_2 t} \mathbf{v}_2 + \cdots + c_n e^{\lambda_n t} \mathbf{v}_n = c_1 \mathbf{x}_1 + c_2 \mathbf{x}_2 + \cdots + c_n \mathbf{x}_n.$$

Check if these $n$ solutions are linearly independent:

$$W[\mathbf{x}_1, \ldots, \mathbf{x}_n] = \det \left( \begin{bmatrix} e^{\lambda_1 t} \mathbf{v}_1 & e^{\lambda_2 t} \mathbf{v}_2 & \cdots & e^{\lambda_n t} \mathbf{v}_n \end{bmatrix} \right)$$

$$= e^{(\lambda_1 + \cdots + \lambda_n) t} \det \left( \begin{bmatrix} \mathbf{v}_1 & \mathbf{v}_2 & \cdots & \mathbf{v}_n \end{bmatrix} \right)$$

$$\neq 0.$$
**Theorem**

*Suppose \( A \) is an \( n \times n \) matrix of real constants. If \( A \) has \( n \) real linearly independent eigenvectors \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \) with corresponding eigenvalues \( \lambda_1, \lambda_2, \ldots, \lambda_n \) (not necessarily distinct), then the vector functions \( \{x_1, x_2, \ldots, x_n\} \) defined by

\[
x_k(t) = e^{\lambda_k t} \mathbf{v}_k, \quad \text{for } k = 1, 2, \ldots, n
\]

are a fundamental set of solutions to \( \mathbf{x}' = A\mathbf{x} \) on any interval. The general solution is

\[
\mathbf{x}(t) = c_1 \mathbf{x}_1 + c_2 \mathbf{x}_2 + \cdots + c_n \mathbf{x}_n.
\]
Example

Find the general solution to $x' = Ax$ if

$$A = \begin{bmatrix} 0 & 2 & -3 \\ -2 & 4 & -3 \\ -2 & 2 & -1 \end{bmatrix}.$$ 

1. Characteristic polynomial is $-(\lambda + 1)(\lambda - 2)^2$.
2. Eigenvalues are $\lambda_1 = -1$ and $\lambda_2 = 2$.
3. Eigenvectors are

   $\lambda_1 = -1 : \quad v_1 = (1, 1, 1),$

   $\lambda_2 = 2 : \quad v_2 = (1, 1, 0), \quad v_3 = (-3, 0, 2).$

4. Fundamental set of solution is

   $$x_1(t) = e^{-t} \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}, \quad x_2(t) = e^{2t} \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix}, \quad x_3(t) = e^{2t} \begin{bmatrix} -3 \\ 0 \\ 2 \end{bmatrix}.$$ 

5. So general solution is

   $$x(t) = c_1 x_1(t) + c_2 x_2(t) + c_3 x_3(t).$$
What happens when $A$ has complex eigenvalues?

If $u = a + ib$ and $v = a - ib$ then

$$a = \frac{u + v}{2} \text{ and } b = \frac{u - v}{2i}.$$  

**Theorem**

Let $u(t)$ and $v(t)$ be real-valued vector functions. If

$$w_1(t) = u(t) + iv(t) \text{ and } w_2(t) = u(t) - iv(t)$$

are complex conjugate solutions to $x' = Ax$, then

$$x_1(t) = u(t) \text{ and } x_2(t) = v(t)$$

are themselves real valued solutions of $x' = Ax$.  

Example

Find the general solution to $\mathbf{x}' = A\mathbf{x}$ where

$$A = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}.$$

1. Characteristic polynomial is $\lambda^2 + 1$.
2. Eigenvalues are $\lambda = \pm i$.
3. Eigenvectors are $\mathbf{v} = (1, \pm i)$.
4. Linearly independent solutions are

$$\mathbf{w}(t) = e^{\pm it} \begin{bmatrix} 1 \\ \pm i \end{bmatrix} = \begin{bmatrix} \cos t \\ -\sin t \end{bmatrix} \pm i \begin{bmatrix} \sin t \\ \cos t \end{bmatrix}.$$

5. Yields the two linearly independent real solutions

$$\mathbf{x}_1(t) = \begin{bmatrix} \cos t \\ -\sin t \end{bmatrix} \quad \text{and} \quad \mathbf{x}_2(t) = \begin{bmatrix} \sin t \\ \cos t \end{bmatrix}.$$
Let's derive the explicit form of the real solutions produced by a pair of complex conjugate eigenvectors.

Suppose \( \lambda = a + ib \) is an eigenvalue of \( A \), with \( b \neq 0 \), corresponding to the eigenvector \( r + is \). This produces the complex solution

\[
\mathbf{w}(t) = e^{(a+ib)t}(r + is)
\]

\[
= e^{at}(\cos bt + i \sin bt)(r + is)
\]

\[
= e^{at}(\cos bt r - \sin bt s) + ie^{at}(\sin bt r + \cos bt s).
\]

Thus, the two real-valued solutions to \( \mathbf{x}' = A \mathbf{x} \) are

\[
\mathbf{x}_1(t) = e^{at}(\cos bt r - \sin bt s),
\]

\[
\mathbf{x}_2(t) = e^{at}(\sin bt r + \cos bt s).
\]

**Remark**

The conjugate eigenvalue \( a - ib \) and eigenvector \( r - is \) would result in the same pair of real solutions.
