## 2. SURFACES

Definition. A subset $S \subset R^{3}$ is a regular surface if, for each point $\mathrm{p} \epsilon \mathrm{S}$, there is an open neighborhood V of $p$ in $R^{3}$, an open set $U \subset R^{2}$ and a map

$$
\mathrm{X}: \mathrm{U} \rightarrow \mathrm{~V} \cap \mathrm{~S},
$$

such that
(1) X is smooth, meaning that if we write

$$
\mathrm{X}(\mathrm{u}, \mathrm{v})=(\mathrm{x}(\mathrm{u}, \mathrm{v}), \mathrm{y}(\mathrm{u}, \mathrm{v}), \mathrm{z}(\mathrm{u}, \mathrm{v})),
$$

then the real-valued functions $x(u, v), y(u, v)$ and $z(u, v)$ have continuous partial derivatives of all orders in $U$.
(2) X is a homeomorphism, meaning that it is a one-to-one correspondence between the points of U and $\mathrm{V} \cap \mathrm{S}$ which is continuous in both directions.
(3) For each point $q \in U$, the linear map

$$
\mathrm{dX}_{\mathrm{q}}: \mathrm{R}^{2} \rightarrow \mathrm{R}^{3}
$$

called the differential of X at q , is one-to-one.

The mapping $\mathrm{X}: \mathrm{U} \rightarrow \mathrm{V} \cap \mathrm{S}$ is called a parametrization or a system of local coordinates for the surface $S$ in the coordinate neighborhood $\mathrm{V} \cap \mathrm{S}$ of p .

For simplicity of notation, we will henceforth use $V$, rather than $\mathrm{V} \cap \mathrm{S}$, to denote an open set on the surface S .

Sphere $x^{2}+y^{2}+z^{2}=r^{2}$

Ellipsoid $x^{2} / \mathbf{a}^{2}+y^{2} / b^{2}+z^{2} / c^{2}=1$

One-sheeted hyperboloid $x^{2}+y^{2}=1+z^{2}$

Two-sheeted hyperboloid $z^{2}=1+\mathbf{x}^{2}+y^{2}$

Torus $(\mathrm{r}-3)^{2}+\mathrm{z}^{2}=1$
in cylindrical ( $\mathbf{r}, \varphi, \mathrm{z}$ )-coordinates

## Nott Torus

This image was developed for the Hudson River Undergraduate Mathematics Conference when it was held at Union College in the spring of 1998. Bill Zwicker, the coordinator of the conference here at Union, requested the design. He used it in the advertising for the conference, and on all the signage during the meeting. It also appeared on the T-shirts that were sold to commemorate the event. For these uses, it was printed either smaller or in lower resolution, so the pixelation that is visible in this large, high-resolution image was not apparent.
The small color version is one of the icons that can appear at the top of the Math Department web site home page $\cdot$; a random image is selected each time the page is loaded. Again, the rough appearance of this version is due to the low resolution necessitated by its use on the web.

## The Catenoid

The Catenoid is the only minimal surface of revolution.

The Helicoid

## The singly periodic Scherk surface

The singly periodic Scherk surface approaches two orthogonal planes.

Here is a variation where the two planes are not orthogonal.

## The doubly periodic Scherk surface

The doubly periodic Scherk surface approaches two families of orthogonal planes.

Here is a variation where the two families are not orthogonal. One can see helicoids forming in the limit!

## The Riemann minimal surface

Riemann found a family of singly periodic minimal surface whose intersections with horizontal planes are circles.

To the right is a pretty degenerate example where one can see two helicoids developing.

## The Enneper surface

The Enneper surface is a complete minimal surface with two straight lines on it. It is not embedded:

From far away, it looks like a plane covering itself three times.

The Willmore bending energy of a surface is the integral (over that surface) of squared mean curvature.

A Willmore surface is a minimum (or any critical point) for this energy.

One way to get a Willmore surface in $\mathrm{R}^{3}$ is to stereographically project a minimal surface in $S^{3}$.

The two surfaces pictured here arise in this way from a pair of conjugate minimal surfaces in $S^{3}$.

Picture and text by John M. Sullivan
torus.math.uiuc.edu/jms/images

Problem 1. What surface is described by the equations

$$
\begin{aligned}
& x=(a \cos \theta+b) \cos \varphi \\
& y=(a \cos \theta+b) \sin \varphi \\
& z=a \sin \theta
\end{aligned}
$$

where $0<\mathrm{a}<\mathrm{b}$ are positive constants, and $\theta$ and $\varphi$ are angular variables?

Draw this surface, and indicate on the drawing what the constants a and b measure.

Problem 2. Let f: $\mathrm{U} \rightarrow \mathrm{R}$ be a smooth real-valued function defined on the open set $U \subset R^{2}$.

The graph of f is the subset of $\mathrm{R}^{3}$ given by

$$
\{(\mathrm{x}, \mathrm{y}, \mathrm{f}(\mathrm{x}, \mathrm{y}):(\mathrm{x}, \mathrm{y}) \in \mathrm{U}\}
$$

Show that the graph of $f$ is a regular surface.

Definition. Let $U$ be an open set of $R^{m}$ and $F: U \rightarrow R^{n}$ a smooth map. A point $p \in U$ is called a critical point of F is the differential $\mathrm{dF}_{\mathrm{p}}: \mathrm{R}^{\mathrm{m}} \rightarrow \mathrm{R}^{\mathrm{n}}$ is not onto. The image $\mathrm{F}(\mathrm{p})$ of a critical point is called a critical value of $F$. A point of $R^{n}$ which is not a critical value of $F$ is called a regular value of F .

Note that any point of $R^{n}$ which is not in the image $F(U)$ is, by default, a regular value of $F$.

Problem 3. Let $U$ be an open subset of $R^{3}$ and $f: U \rightarrow R$ a smooth function. If a is a regular value of $f$, show that $f^{-1}(a)$ is a regular surface in $R^{3}$.
Hint. Use the inverse function theorem.

Problem 4. Show that 1 is a regular value of the function

$$
\mathrm{f}(\mathrm{x}, \mathrm{y}, \mathrm{z})=\mathrm{x}^{2} / \mathrm{a}^{2}+\mathrm{y}^{2} / \mathrm{b}^{2}+\mathrm{z}^{2} / \mathrm{c}^{2}
$$

and conclude that the ellipsoid

$$
x^{2} / a^{2}+y^{2} / b^{2}+z^{2} / c^{2}=1
$$

is a regular surface.

Problem 5. Let $S$ be a regular surface in $R^{3}$ and $p \in S$. Show that there is a neighborhood $V$ of $p$ in $S$ which is the graph of a differentiable function having one of the following three forms:

$$
z=f(x, y), y=g(x, z), x=h(y, z) .
$$

## Problem 6 (Change of parameters). Let

$$
\mathrm{X}_{1}: \mathrm{U}_{1} \rightarrow \mathrm{~V}_{1} \quad \text { and } \quad \mathrm{X}_{2}: \mathrm{U}_{2} \rightarrow \mathrm{~V}_{2}
$$

be two parametrizations of the regular surface $S$, and suppose that the point $p$ of $S$ lies in the image of both:

$$
\mathrm{p} \epsilon \mathrm{~W}=\mathrm{X}_{1}\left(\mathrm{U}_{1}\right) \cap \mathrm{X}_{2}\left(\mathrm{U}_{2}\right)=\mathrm{V}_{1} \cap \mathrm{~V}_{2}
$$

Show that the map

$$
\mathrm{X}_{2}^{-1} \mathrm{X}_{1}: \mathrm{X}_{1}^{-1}(\mathrm{~W}) \rightarrow \mathrm{X}_{2}^{-1}(\mathrm{~W})
$$

is a diffeomorphism (that is, a one-to-one correspondence which is smooth in both directions).

Definition. Let $f: S \rightarrow R$ be a real-valued function defined on the regular surface $S$ in $R^{3}$. We will say that f is smooth if for every parametrization $\mathrm{X}: \mathrm{U} \rightarrow \mathrm{V}$ of an open set V on S , the composite $\operatorname{map} \mathrm{f} \circ \mathrm{X}: \mathrm{U} \rightarrow \mathrm{R}$ is smooth.

Problem 7. Show that to check that a given real-valued function $\mathrm{f}: \mathrm{S} \rightarrow \mathrm{R}$ is smooth, you don't really have to check that the compositions $\mathrm{f} \circ \mathrm{X}$ are smooth for all parametrizations X of S . It's enough to do it for any family of parametrizations whose images cover $S$.

Problem 8. Let $S$ be a regular surface in $\mathrm{R}^{3}$, let V be an open subset of $R^{3}$ which contains $S$, and let $\mathrm{f}: \mathrm{V} \rightarrow \mathrm{R}$ be a smooth function. Show that the restriction of $f$ to $S$ is also a smooth function.

Problem 9. Given two surfaces $S_{1}$ and $S_{2}$ in $R^{3}$ and a map f: $\mathrm{S}_{1} \rightarrow \mathrm{~S}_{2}$.

Figure out how to use parametrizations of $S_{1}$ and $S_{2}$ to define smoothness of $f$.

## The tangent plane to a regular surface at a point.

Definition. Let $S$ be a regular surface in $R^{3}$ and p a point of $S$. Pick any parametrization of $S$, $\mathrm{X}: \mathrm{U} \rightarrow \mathrm{V} \cap \mathrm{S}$, with p lying in the open set $\mathrm{V} \cap \mathrm{S}$. Let q be the unique point of U such that $\mathrm{X}(\mathrm{q})=\mathrm{p}$. The linear map $d X_{q}: R^{2} \rightarrow R^{3}$, that is, the differential of $X$ at $q$, is one-to-one, and hence its image, $\mathrm{dX}_{\mathrm{q}}\left(\mathrm{R}^{2}\right)$, is a 2-dimensional subspace of $\mathrm{R}^{3}$. We call this the tangent space to $\mathbf{S}$ at $\mathbf{p}$, and denote it by $\mathrm{T}_{\mathrm{p}} \mathrm{S}$.

Problem 10. Show that this definition of $T_{p} S$ is independent of the choice of parametrization X .

The common convention is to draw the tangent space to $S$ at $p$ so that it goes through $p$ rather than through the origin, and simply remember that it is a vector space.

Problem 11. Let $S$ be a regular surface in $R^{3}$. Show that the tangent space to $S$ at $p$ consists of the tangent vectors at $p$ to all the regular curves which lie on $S$ and go through $p$.

Problem 12. If $S_{1}$ and $S_{2}$ are regular surfaces in $R^{3}$ and $f: S_{1} \rightarrow S_{2}$ is a smooth map, show how to define its differential

$$
\mathrm{df}_{\mathrm{p}}: \mathrm{T}_{\mathrm{p}} \mathrm{~S}_{1} \rightarrow \mathrm{~T}_{\mathrm{f}(\mathrm{p})} \mathrm{S}_{2} .
$$

Then prove the chain rule for the differentials of smooth maps between regular surfaces in $\mathrm{R}^{3}$.

Problem 13. Suppose f: $S_{1} \rightarrow S_{2}$ is a smooth map between regular surfaces in $R^{3}$. Suppose that at the point $p \in S_{1}$, the differential $\mathrm{df}_{\mathrm{p}}: \mathrm{T}_{\mathrm{p}} \mathrm{S}_{1} \rightarrow \mathrm{~T}_{\mathrm{f}(\mathrm{p})} \mathrm{S}_{2}$ is an isomorphism.

Prove that f is a diffeomorphism from some open neighborhood of p on $\mathrm{S}_{1}$ to some open neighborhood of $f(p)$ on $S_{2}$.

## The first fundamental form.

Let $S$ be a regular surface in $R^{3}$ and $p \in S$. Then the tangent plane $T_{p} S$ to $S$ at $p$ is a 2-dimensional subspace of $\mathrm{R}^{3}$, meaning that it is a 2-plane passing through the origin, even though when drawing it, we usually move it parallel to itself so that it passes through the point p .

Thus $T_{p} S$ inherits an inner product $<,>_{p}$ from $R^{3}$, and if $W_{1}$ and $W_{2}$ are two tangent vectors to $S$ at $p$, their inner product is written as $\left\langle\mathrm{W}_{1}, \mathrm{~W}_{2}\right\rangle_{\mathrm{p}}$.

The inner product $\left\langle\mathrm{W}_{1}, \mathrm{~W}_{2}\right\rangle_{\mathrm{p}}$ is a symmetric bilinear form on the tangent space $T_{p} S$, meaning that it is a map

$$
<,>_{\mathrm{p}}: \mathrm{T}_{\mathrm{p}} \mathrm{~S} \times \mathrm{T}_{\mathrm{p}} \mathrm{~S} \rightarrow \mathrm{R}
$$

which is linear in each of the arguments $\mathrm{W}_{1}$ and $\mathrm{W}_{2}$ when the other is held fixed, and that

$$
\left\langle\mathrm{W}_{1}, \mathrm{~W}_{2}\right\rangle_{\mathrm{p}}=\left\langle\mathrm{W}_{2}, \mathrm{~W}_{1}\right\rangle_{\mathrm{p}}
$$

The associated quadratic form

$$
\mathrm{I}_{\mathrm{p}}: \mathrm{T}_{\mathrm{p}} \mathrm{~S} \rightarrow \mathrm{R}
$$

is defined by

$$
\mathrm{I}_{\mathrm{p}}(\mathrm{~W})=\langle\mathrm{W}, \mathrm{~W}\rangle_{\mathrm{p}} .
$$

Note that the original bilinear form $<,>_{p}$ can be recovered from the associated quadratic form because
$\mathrm{I}_{\mathrm{p}}\left(\mathrm{W}_{1}+\mathrm{W}_{2}\right)=\left\langle\mathrm{W}_{1}+\mathrm{W}_{2}, \mathrm{~W}_{1}+\mathrm{W}_{2}\right\rangle$
$=\left\langle\mathrm{W}_{1}, \mathrm{~W}_{1}\right\rangle+\left\langle\mathrm{W}_{1}, \mathrm{~W}_{2}\right\rangle+\left\langle\mathrm{W}_{2}, \mathrm{~W}_{1}\right\rangle+\left\langle\mathrm{W}_{2}, \mathrm{~W}_{2}\right\rangle$
$=\mathrm{I}_{\mathrm{p}}\left(\mathrm{W}_{1}\right)+2\left\langle\mathrm{~W}_{1}, \mathrm{~W}_{2}\right\rangle+\mathrm{I}_{\mathrm{p}}\left(\mathrm{W}_{2}\right), \quad$ and hence
$\left\langle\mathrm{W}_{1}, \mathrm{~W}_{2}\right\rangle=1 / 2\left(\mathrm{I}_{\mathrm{p}}\left(\mathrm{W}_{1}+\mathrm{W}_{2}\right)-\mathrm{I}_{\mathrm{p}}\left(\mathrm{W}_{1}\right)-\mathrm{I}_{\mathrm{p}}\left(\mathrm{W}_{2}\right)\right)$.

Thus there is no loss of information in focusing on the associated quadratic form, and on the plus side we gain in notational symplicity because we only have to evaluate it on one vector $W$ instead of on two, $W_{1}$ and $W_{2}$.

Definition. The quadratic form $\mathrm{I}_{\mathrm{p}}(\mathrm{W})=\langle\mathrm{W}, \mathrm{W}\rangle_{\mathrm{p}}$ is called the first fundamental form of the regular surface $S$ at the point $p$.

The first fundamental form simply encodes how the surface $S$ inherits the natural inner product of $R^{3}$.

We will see shortly that the first fundamental form allows us to make geometric measurements on the surface, such as lengths of curves, angles between tangent vectors, and areas of regions on the surface, without referring to the ambient space $R^{3}$ where the surface lies.

We will see later that the first fundamental form also encodes some, but not all, of the information about the "curvature" of the surface in $\mathrm{R}^{3}$.

## Notation for tangent vectors to S .

Let $S$ be a surface in $R^{3}$ and $p$ a point of $S$.
Let $\mathrm{X}: \mathrm{U} \rightarrow \mathrm{V}$ be a parametrization of a neighborhood V of $p$ on $S$, and let ( $u, v$ ) be Euclidean coordinates on $U$.

If $(u(t), v(t))$ describes a curve in $U$, then $X(u(t), v(t))$ describes its image on $S$.

If $\left(u^{\prime}(t), v^{\prime}(t)\right)$ is the velocity vector to the curve in $U$, then

$$
X^{\prime}(t)=X_{u} u^{\prime}(t)+X_{v} v^{\prime}(t)
$$

is the velocity vector to the image curve on $S$, and hence a tangent vector to $S$ at the point $\mathrm{p}=\mathrm{X}(\mathrm{u}(\mathrm{t}), \mathrm{v}(\mathrm{t}))$.

The vector partial derivatives $X_{u}$ and $X_{v}$ provide a basis for the tangent space $T_{p} S$.

## Notation for the first fundamental form.

Let $\mathrm{W}=\mathrm{X}_{\mathrm{u}} \mathrm{u}^{\prime}+\mathrm{X}_{\mathrm{v}} \mathrm{v}^{\prime}$ be a tangent vector to S at p , as just explained.

Then evaluating the first fundamental form $I_{p}$ on $W$, we get
$\mathrm{I}_{\mathrm{p}}(\mathrm{W})=\langle\mathrm{W}, \mathrm{W}\rangle_{\mathrm{p}}$
$=\left\langle X_{u} u^{\prime}+X_{v} v^{\prime}, X_{u} u^{\prime}+X_{v} v^{\prime}\right\rangle_{p}$
$=\left\langle X_{u}, X_{u}\right\rangle_{p}\left(u^{\prime}\right)^{2}+2\left\langle X_{u}, X_{v}\right\rangle u^{\prime} v^{\prime}+\left\langle X_{v}, X_{v}\right\rangle\left(v^{\prime}\right)^{2}$
$=E(u, v)\left(u^{\prime}\right)^{2}+2 F(u, v) u^{\prime} v^{\prime}+G(u, v)\left(v^{\prime}\right)^{2}$.

The three real-valued functions

$$
\begin{aligned}
& \mathrm{E}(\mathrm{u}, \mathrm{v})=\left\langle\mathrm{X}_{\mathrm{u}}, \mathrm{X}_{\mathrm{u}}\right\rangle, \\
& \qquad \begin{aligned}
& \mathrm{F}(\mathrm{u}, \mathrm{v})=\left\langle\mathrm{X}_{\mathrm{u}}, X_{\mathrm{v}}\right\rangle, \\
& G(\mathrm{u}, \mathrm{v})=\left\langle\mathrm{X}_{\mathrm{v}}, \mathrm{X}_{\mathrm{v}}\right\rangle
\end{aligned}
\end{aligned}
$$

encode complete information about the first fundamental form throughout the given coordinate neighborhood on S .

Notice that we have dropped the subscript p from the notation for the inner product, since it is clear from context.

## Examples.

- Consider the xy-coordinate plane in $\mathrm{R}^{3}$ as a surface S parametrized by itself:

$$
X(u, v)=(u, v, 0)
$$

Then $X_{u}=(1,0,0)$ and $X_{v}=(0,1,0)$, hence

$$
\begin{aligned}
& \mathrm{E}(\mathrm{u}, \mathrm{v})=\left\langle\mathrm{X}_{\mathrm{u}}, \mathrm{X}_{\mathrm{u}}\right\rangle=1 \\
& \mathrm{~F}(\mathrm{u}, \mathrm{v})=\left\langle\mathrm{X}_{\mathrm{u}}, X_{\mathrm{v}}\right\rangle=0 \\
& \mathrm{G}(\mathrm{u}, \mathrm{v})=\left\langle\mathrm{X}_{\mathrm{v}}, X_{\mathrm{v}}\right\rangle=1 .
\end{aligned}
$$

- Consider the torus of revolution in $\mathrm{R}^{3}$ as a surface S parametrized by
$X(\theta, \varphi)=((a \cos \theta+b) \cos \varphi,(a \cos \theta+b) \sin \varphi, a \sin \theta)$.
Then
$X_{\theta}=(-a \sin \theta \cos \varphi,-a \sin \theta \sin \varphi, a \cos \theta)$
$X_{\varphi}=(-(a \cos \theta+b) \sin \varphi,(a \cos \theta+b) \cos \varphi, 0)$,

$$
\begin{aligned}
& \mathrm{E}(\theta, \varphi)=\left\langle\mathrm{X}_{\theta}, \mathrm{X}_{\theta}\right\rangle=\mathrm{a}^{2} \\
& \mathrm{~F}(\theta, \varphi)=\left\langle\mathrm{X}_{\theta}, \mathrm{X}_{\varphi}\right\rangle=0 \\
& \mathrm{G}(\theta, \varphi)=\left\langle\mathrm{X}_{\varphi}, \mathrm{X}_{\varphi}\right\rangle=(\mathrm{a} \cos \theta+\mathrm{b})^{2}
\end{aligned}
$$

- Consider the unit 2-sphere $S^{2}$ in $\mathrm{R}^{3}$ parametrized by

$$
X(\theta, \varphi)=(\sin \theta \cos \varphi, \sin \theta \sin \varphi, \cos \theta)
$$

The parametrization is singular when $\theta=0$ (north pole) and when $\theta=\pi$ (south pole), so we restrict $0<\theta<\pi$.

To make the parametrization one-to-one rather than many-to-one, we can require that $0<\varphi<2 \pi$.

Then

$$
X_{\theta}=(\cos \theta \cos \varphi, \cos \theta \sin \varphi,-\sin \theta)
$$

$$
X_{\varphi}=(-\sin \theta \sin \varphi, \sin \theta \cos \varphi, 0)
$$

$\mathrm{E}(\theta, \varphi)=\left\langle\mathrm{X}_{\theta}, \mathrm{X}_{\theta}\right\rangle=1$
$F(\theta, \varphi)=\left\langle X_{\theta}, X_{\varphi}\right\rangle=0$
$G(\theta, \varphi)=\left\langle X_{\varphi}, X_{\varphi}\right\rangle=\sin ^{2} \theta$.

## Arc length of curves on a surface.

Let $\mathrm{X}: \mathrm{U} \rightarrow \mathrm{V} \subset \mathrm{S}$ be a parametrization of a portion of the regular surface $S$ in $R^{3}$.

Give a curve on $S$, the portion of it which runs within the open set V can be expressed as $\mathrm{X}(\mathrm{u}(\mathrm{t}), \mathrm{v}(\mathrm{t}))$, where $(u(t), v(t))$ is a curve in $U$.

The arc length $s$ of this curve is then given by

$$
\begin{aligned}
s & =\int|d X / d t| d t=\int\left\langle X^{\prime}(t), X^{\prime}(t)\right\rangle^{1 / 2} d t \\
& =\int I\left(X^{\prime}(t)\right)^{1 / 2} d t \\
& =\int\left[E(u, v)\left(u^{\prime}\right)^{2}+2 F(u, v) u^{\prime} v^{\prime}+G(u, v)\left(v^{\prime}\right)^{2}\right]^{1 / 2} d t .
\end{aligned}
$$

In view of this, it is customary to write

$$
\mathrm{ds}^{2}=\mathrm{Ed} \mathrm{u}^{2}+2 \mathrm{Fdu} \mathrm{dv}+\mathrm{Gdv}^{2}
$$

as a short hand for the formula
$(\mathrm{ds} / \mathrm{dt})^{2}=\mathrm{E}(\mathrm{du} / \mathrm{dt})^{2}+2 \mathrm{~F}(\mathrm{du} / \mathrm{dt})(\mathrm{dv} / \mathrm{dt})+\mathrm{G}(\mathrm{dv} / \mathrm{dt})^{2}$.

Problem 14. Let $X: U \rightarrow V \subset S$ be a parametrization of a portion of the regular surface $S$ in $R^{3}$. The image under X of the curves $\mathrm{u}=$ constant and $\mathrm{v}=$ constant are called the coordinate curves on V . Show that the angle $\theta(\mathrm{u}, \mathrm{v})$ between these curves is given by

$$
\cos \theta(\mathrm{u}, \mathrm{v})=\mathrm{F}(\mathrm{u}, \mathrm{v}) / \sqrt{ }(\mathrm{E}(\mathrm{u}, \mathrm{v}) \mathrm{G}(\mathrm{u}, \mathrm{v}))=\mathrm{F} / \sqrt{ }(\mathrm{EG}) .
$$

Problem 15. Let $\mathrm{X}: \mathrm{U} \rightarrow \mathrm{V} \subset \mathrm{S}$ be a parametrization of a portion of the regular surface $S$ in $R^{3}$. Let $U_{o}$ be a subdomain of $U$ and $V_{o}=X\left(U_{0}\right)$ the corresponding subdomain of V in S . Justify the formula

$$
\operatorname{area}\left(V_{o}\right)=\int U_{o}\left|X_{u} \times X_{v}\right| d u d v,
$$

and use it to compute the total surface area of the unit 2-sphere $\mathrm{S}^{2} \subset \mathrm{R}^{3}$.

Problem 16. Use this same formula to compute the total surface area of the torus of revolution
$X(\theta, \varphi)=((a \cos \theta+b) \cos \varphi,(a \cos \theta+b) \sin \varphi, a \sin \theta)$,
where $0<\mathrm{a}<\mathrm{b}$.
